The Bradford Chemical Society, in conjunction with the Department of Chemistry and Dyeing of the Technical College, Bradford, and the Yorkshire Council for Further Education, is arranging a symposium on radiochemistry and an exhibition of radiochemical and chemical apparatus, to be held in the Technical College, Bradford, during February 17–18. The symposium will take the form of a short course on the subject, and four lectures will be given, as follows: basic principles of radiochemistry (Dr. G. B. Cook), measurement of beta- and gamma-radiation (Dr. D. Taylor), estimation of isotope concentrations (A. A. Smales) and applications to chemical problems (Dr. D. R. Stranks). The symposium and exhibition will be open, without charge, but to help in the arrangement of accommodation for lectures and demonstrations, intending visitors are requested to inform Dr. W. R. Moore, of the Department of Chemistry and Dyeing, Technical College, Bradford, to whom all inquiries should be addressed.

The Night Sky in February

New moon occurs on Feb. 11d. 21h. 38m., U.T., and full moon on Feb. 26d. 01h. 41m. The following conjunctions with the Moon take place: Feb. 5d. 05h., Saturn 3° N.; Feb. 6d. 07h., Mars 0·2° N.; Feb. 9d. 22h., Mercury 1° S.; Feb. 15d. 11h., Venus 6° S.; Feb. 25d. 11h., Jupiter 6° N. Mercury rises about 7h. at the beginning of the month and is then too close to the Sun for observation, but at the middle and end of the month it rises at 6h. 10m., in the former case more than an hour before sunrise and may be visible for a short period though it lies rather low for good observation in the British Isles. Venus sets at 20h. 10m., 20h. 45m. and 21h. 30m. at the beginning, middle and end of the month, respectively; its stellar magnitude varies between −3·5 and −3·6 and the visible portion of its illuminated disk between 0·793 and 0·705 during the month, its distance from the Earth during this period varying from 113 to 96 million miles. Mars rises shortly before 4h. during February. Its eastward motion through Ophiuchus into Sagittarius and its position a little south of μ Sagittarii at the end of the month is easily observed, though it lies rather far south for good observation during this time; its stellar magnitude varies from 1·5 to 1·2, due to its distance from the Earth decreasing from 170 to 147 million miles during February. Jupiter rises early in the evening and is visible throughout the night, setting at 8h. 30m., 7h. 30m. and 6h. 30m. on February 1, 15 and 29, respectively, and is a conspicuous object (stellar magnitude −2·1) in the constellation Leo, in which it has a westward motion. Saturn rises at 2h. 55m., 2h. 05m. and 1h. 15m. at the beginning, middle and end of the month, respectively, and lies a little north of β and γ Scorpii, but is too low for good observation in the British Isles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Feb. 1d. 01h. 32·0m., *q* Vir. (*R*); Feb. 14d. 18h. 25·5m., 19 Psc. (*D*); Feb. 19d. 20h. 10·9m., 51 Tau. (*D*); Feb. 19d. 20h. 55·7m., 56 Tau. (*D*); Feb. 20d. 00h. 34·4m., 247*B* Tau. (*D*); Feb. 20d. 19h. 42·7m., *n* Tau. (*D*); Feb. 20d. 23h. 47·6m., o Tau. (*D*); Feb. 23d. 22h. 25·6m., 29 Cnc. (*D*); Feb. 24d. 23h. 57·7m., ω Leo *m* (*D*). *R* and *D* refer to reappearance and disappearance, respectively.

Announcements

The first award of the William Froude Medal of the Institution of Naval Architects has been made to Sir Thomas Havelock, lately professor of mathematics in the University of Durham (King's College, Newcastle upon Tyne). The William Froude Memorial Fund was launched by the Institution in 1952 to enable a plaque to be placed on the site of the original experimental tank at Torquay and to publish Froude's technical papers. These have been done, and from the small balance still remaining in the Fund the Institution will offer this gold medal from time to time for "some outstanding contribution to naval architecture and shipbuilding".

The Zoological Society of India has awarded the Sir Dorab Tata Gold Medal to Dr. M. L. Roonwal, forest entomologist in the Forest Research Institute, Dehra Dun, for his contributions to zoology during 1952–54. Dr. M. L. Roonwal's work has been concerned with termites and Teredinid boring bivalves in relation to forestry, and also with phase-transformation and population dynamics of the desert locust.

Prof. P. W. Richards, professor of botany in the University College of North Wales, Bangor, and Mr. H. Wardale, a Northumberland hill farmer, have been appointed to the National Parks Commission. Brigadier P. B. E. Acland, Dr. Nancy G. Davies and Mr. W. B. Yapp have been re-appointed members of the Commission. Prof. R. C. McLean has resigned.

Prof. E. G. White, professor of veterinary preventative medicine in the University of Liverpool, has been appointed a member of the Agricultural Improvement Council for England and Wales to fill the vacancy created by the death of Prof. F. Blakemore.

Dr. Jesse E. Hobson, director since March 1948 of the Stanford Research Institute, Menlo Park, California, is resigning because of ill health. Dr. Hobson, who is an electrical engineer, was director of the Armour Research Foundation for four years prior to his appointment to the Stanford Research Institute. At that time the staff of the Institute numbered less than fifty and its research budget 250,000 dollars a year; it is a tribute to Dr. Hobson's leadership that during the past eight years the Institute has grown to a staff of twelve hundred and a budget of 10½ million dollars.

Mr. Ralph H. Atkinson has retired as head of the Platinum Metals Section of the Research Laboratory at Bayonne, New Jersey, of the International Nickel Company. A graduate of the University of Cambridge, Mr. Atkinson was a lecturer in chemistry and metallurgy at Cambridge before joining the Mond Nickel Company in 1923 as assistant manager of its platinum metals refinery. He moved to Canada early in 1940 and has held a number of appointments there and in the United States, mainly with affiliated organizations of the International Nickel Company. His research at Bayonne has been on metallurgical and electrochemical problems in connexion with the applications of the platinum family of metals, with special regard to the soldering and casting of palladium.

A memorial service for Prof. A. O. Rankine, emeritus professor of physics in the Imperial College of Science and Technology, London, who died on January 20, will be held in the Queen's Chapel of the Savoy, London, W.C.2, on February 2 at noon.

FIRST INTERNATIONAL CONGRESS ON DOCUMENTATION OF APPLIED CHEMISTRY

THE First International Congress on Documentation of Applied Chemistry was held in London at the Institut Français, South Kensington, during November 22–25, and at the final session its claim to the title "First" was substantiated when the members, by a substantial majority, agreed to recommend that the International Union of Pure and Applied Chemistry, which sponsored the meeting, should sponsor the "Second" in about three years time. It was abundantly clear that this Congress had not been called any too soon. As the president of honour, Lord Cherwell, said, when he spoke at the opening session, he was appalled, in general, at the rate of change going on in the world and, in particular, at the rate at which scientific literature is increasing; he charged the Congress with the task of finding the best ways of putting this mass of information at people's disposal.

The first morning session was devoted to the international scene, with Dr. L. H. Lampitt as chairman. A general survey was given by Prof. H. R. Kruyt, whose broad outlook on international matters is so well known; he made a plea, not new but still as urgent as ever, for abstracting, which is a service to the whole world, to be organized on an international footing. Prof. G. A. Boutry then spoke on the Abstracting Board of the International Council of Scientific Unions, which has done so much for speeding up the publication of abstracts. Its work, however, is not well known to chemists as its initial efforts have been directed towards physics abstracting, but it is now concerning itself with chemical abstracts. Prof. Boutry said that authors' summaries are used in the case of about a third of the world's physics papers; this led to considerable argument as to the value of authors' abstracts and to a general discussion on the various purposes for which abstracts were required, the abstracting of 'letters to the editor', of patents and of 'semi'-publications (brochures, technical advertisements, etc.).

When Dr. Lampitt introduced Dr. N. Grell, who read a communication from M. R. Grégoire, of the Organization for European Economic Co-operation, he said that relatively few people know what the European Productivity Agency is or what it does. Dr. Grell gave an interesting survey of the work of the Agency, the aim of which is to improve the standard of living through increased productivity, and of its publications, notably its "Technical Digests". To M. Jean Gérard's criticism that this information is not of the kind required by research workers, Dr. Grell emphasized that their readers range from scientists to factory workers. Prof. P. Auger, of the United Nations Educational, Scientific and Cultural Organization (Unesco), then gave a résumé of the scientific programme of his Organization, Dr. Lampitt emphasizing how difficult it had been to "get the 'S' put into UNESCO". The incentives for peace, said Prof. Auger, are one language and one fight: science is always a universal language; and the common fight is that against the adverse forces of Nature. Unesco's aim, he said, is to strengthen the links between the world's scientists, to organize the meeting of scientists and to create international bodies. This stimulating paper led to a long discussion on *rapprochement* with the U.S.S.R., which the chairman had to restrain; but, to an onslaught on lack of collaboration, led by Dr. D. J. Urquhart, Prof. Auger replied laconically, "There is hope", while the spokesman for the Russian delegation hinted that co-operation is on the way.

The afternoon session, under the chairmanship of Sir Alfred Egerton, reviewed the national scene, and this was a full afternoon's programme as papers were read by the representatives of seven nations. Prof. J. Wyart (France) advocated, not without criticism, machine-made abstracts to improve further an already improving situation in French documentation; Prof. E. Velander (Sweden), reading a paper on behalf of Mr. E. Engel, who was ill, reported excellent co-operation on documentation between the Scandinavian countries; and Dr. J. M. Meyer showed how a small country like Switzerland has to rely on international documentation and how valuable *Chemical Abstracts* and *Chemisches Zentralblatt* are to his country. Dr. M. G. Mellon (Purdue University), in his review of the situation in the United States, pointed out that he now teaches a course in chemical literature for which up to a hundred and fifty students enrol and that such courses are now held in about twenty-five out of several hundred American colleges; one speaker afterwards pressed for students to be taught the value of abstracts. Dr. U. V. Panov (U.S.S.R.) promised co-operation between Russia and the West, the difficulties of transliteration being freely admitted, while Dr. A. Gorter (Holland) lamented the limited application of the Dutch language in documentation.

Only Dr. D. J. Urquhart among the national speakers stirred up controversy, when speaking for Great Britain. Claiming that chemistry is in the vanguard of scientific information, he contended that the quantity of literature will outgrow our intellectual resources and that sooner or later there will be a shortage of scientists. The under-developed countries will then contribute more, and he appealed for a *lingua scientifica* in order to cope with it.

Prof. Velander was chairman of the first session on the second day, when the whole day was given up to particular problems. An excellent start was made with Prof. R. R. Shaw's vivid description of his "Scarecrow Press", strangely enough a serious publishing concern aiming at printing scholarly books where the required edition is as low as 1,500–300 copies, or even as low as twenty-five copies, and would not therefore be considered by ordinary publishing firms. He described how he had aimed at cutting costs to the minimum, and he contended that for scientific books the authorship, editing, etc., should be free and that only the actual production of the book should be charged. Instances were given where valuable but highly specialized books are at a prohibitive price. Dr. E. B. Hughes, deputy chief chemist of J. Lyons and Co., speaking on abstracts, said how important it is to get the abstracts to the chemist, and he advocated selective abstracts, as the average research chemist cannot afford volumes like *Chemical Abstracts*, valuable as they are. He introduced a wistful note in lamenting the passing of the high-quality abstracts of the Chemical Society of thirty-five years ago. Dr. V. V. Serpinsky, editor of the *Russian Chemistry Abstracts Journal*, speaking on the same subject, emphasized how young his journal is, but he believed that it will ultimately make a useful contribution. In the discussion on abstracts that followed, doubt was again expressed on the value of authors' abstracts, and the need was stressed for experience and specialized training in abstracting: Dr. Grell favoured 'digests', bigger than abstracts, and therefore on a more limited scale.

Dr. B. Agard-Evans, Ministry of Works librarian, discussed special documents, having in mind pamphlets and the like, the technical content of which is often important and yet often lost. His organization, he said, in spite of much expense and labour, covers only about 25 per cent of such publications from abroad.

At the next session, with Prof. A. Nasini (University of Turin) in the chair, Prof. M. Lora-Tamayo (University of Madrid) described with great effect the problem of language, with examples of the technical terms in the steel and other industries in English, Spanish and other tongues; any language, he said, even if safeguarded in its purity, is confronted with invasion of foreign technical terms. Dr. J. E. Holmstrom (Unesco) talked on multilingual technical dictionaries which he held to be indispensable, although he warned the Congress that existing ones are deficient in many respects and that the creation of new ones is difficult. To this end Dr. R. S. Cahn stressed that of nineteen thousand papers on chemistry in 1954, 60 per cent were in English, 13 per cent in German, 9 per cent in Russian, 7 per cent in French, and smaller proportions in Japanese, Italian, Spanish, Portuguese and others. The theme of the paper by Dr. E. Pietsch (director of the Gmelin Institute) was whether man can produce a store of facts greater than the human brain by extrahuman systems; he elaborated many of the mechanical methods, electronic systems, punched-card systems, microfilms and so on, and gave examples of the use of International Business Machine cards.

Dr. E. J. Crane (editor of *Chemical Abstracts*) said, on the subject of indexing, that for every thousand words of abstracts there now has to be seven hundred words of index. He insisted that trained abstractors are essential, for though machines are useful, they have to rely on accurate information being fed to them. A discussion on subject-indexing followed, and Dr. Crane intimated that the new building for *Chemical Abstracts* would have facilities for research into methods. The session ended with a paper on library and technical information services by Miss Elin Törnudd (Finland), the only woman contributor. "The customer is always right," she said, and inquiries have shown that 90 per cent of potential users of the lists of titles in her information bulletins in Finland do in fact use them; 70 per cent are in favour of not translating titles, except those in Russian. This was confirmed by one speaker on fuel abstracts, who said that speed in publication of titles is more important than the actual abstracts.

Prof. W. A. Noyes (editor of the *Journal of the American Chemical Society*) adroitly controlled from the chair a fast-moving session on the third morning of the Congress. After Prof. A. Scortecci's paper on the role of governments in organizing documentary information services, Prof. Noyes asked whether such services should be centralized, but Prof. Scortecci contended that separate subjects are so specialized that they should be left to the specialists. He agreed, however, that a general classification of information is desirable but that special fields require special classifications. Dr. R. E. Fairbairn (Imperial Chemical Industries, Ltd.), in the absence of the author, Mr. J. D. Rose (of the same firm), read a paper on the role of industry. In a provocative speech he contended that abstracts are too late for current information and that inadequate indexing makes search for past information unreliable; in spite of a protest from Dr. Crane, he insisted that abstract indexes are anything up to five years late. A spirited discussion followed on what the users of abstracts in industry really want, and it was generally agreed that the great need is for current information services.

A stimulating paper on the role of professional and learned societies was given by Dr. Cahn, editor to the Chemical Society, in which he demanded the reorganization of publishing methods, cuts in costs, greater support from industry and a users' conference; the financial position of professional societies is serious, he said, although there is no shortage of manuscripts for publication. The last paper of the session was a thoughtful contribution by Dr. J. Knox (Department of Scientific and Industrial Research) on "How can Further Co-operation Take Place ?", to which M. Jean Gérard replied at length.

The final session opened with a paper by Mr. A. W. Marsden, director of the Commonwealth Bureau of Dairy Science, on the often-forgotten subject of chemistry applied to agriculture and on the information services provided by the Commonwealth Agricultural Bureaux. He was followed by a talk by Mr. N. M. Javaronkov, of the Russian delegation, the theme of which—collaboration—was taken up enthusiastically by the meeting. A small voice mentioned, for the only time during the whole Congress, the possibility of Esperanto to overcome language difficulties.

A brilliant summary of the proceedings of the Congress was given by Mr. F. P. Dunn, honorary publications secretary of the Society of Chemical Industry, in which he concluded with a list of the suggested resolutions put forward by various delegates during the six sessions. Dr. L. H. Lampitt, chairman of the final session, sought the advice of the meeting as to what positive action the Congress should take to implement the results of its discussions. A vigorous minority wanted to discuss the eight individual resolutions one by one, but the meeting decided, by a substantial majority, to put up two resolutions: first, that the International Union of Pure and Applied Chemistry, the sponsoring body, should call a second Congress in about three years time; and secondly, that Mr. Dunn's summary of the proceedings and the headings of recommendations enumerated by him be referred to the Organizing Committee of the Congress for submission to the Union.

There is no doubt that this Congress served a very useful and, above all, a timely purpose. The increase in scientific literature, on applied chemistry alone, is terrifying and, although at this Congress much time was wasted by some boring repetition and by many people grinding their personal axes, the general feeling that international co-operation and the application of the most modern methods of documentation are the solutions was echoed by Sir William Ogg, the chairman of the Congress Council, in his valedictory address. Two points he made were that, although English used to be international and is still nearly the *lingua scientifica*, scientists must learn more languages, not only Russian, and that consideration should be given to the fact that, whereas in the U.S.S.R. scientific documentation is a State matter, in Great Britain it is dependent on industry and the business houses.

The success of the Congress was borne out by the attendance of more than three hundred delegates, about one-third of whom were from overseas. There was a full programme of excellent social events.

SCIENCE MASTERS' ASSOCIATION

ANNUAL MEETING IN LONDON

ABOUT a thousand science masters met in London at the Royal College of Science, South Kensington, for four days in the week between Christmas and New Year, the occasion being the annual meeting of the Science Masters' Association. Residential accommodation was provided, as usual, at Queen Elizabeth College, Campden Hill Road, which also entertained visitors in its laboratories on two evenings. Teachers were present from the Netherlands, Natal, Pakistan and India, and Unesco sent an observer.

For his presidential address, Sir Edward Salisbury, director of the Royal Botanic Gardens, Kew, chose the theme "Science and Education". He began by saying that his life had been spent in the study of ecology, from varied approaches, and that this might have been no bad preparation for suggesting ways in which the disciplines derived from different studies might be integrated. The greatest danger to real education, he said, is to mistake the provision of information for the imparting of knowledge; it is much easier to acquire strands of information than to weave them into a harmonious whole. Science teaching should therefore stress the structural unity of all knowledge. He recalled that the test he applied when he taught botany students was to ask whether their studies made a walk in the country more interesting; if not, they should try some other subject. He thought that a similar test might well be applied to all learning: Does it make life richer and more colourful?

A marriage of science and the humanities is essential to the success of the civilization of the future, and in order to achieve this, Sir Edward thought that the scientist should write good English and that the humanist should take the trouble to understand him. He deplored the passing of the general use of the Bible, which had set a standard of English expression, not less valuable because often unconsciously acquired. Science, he went on, should set itself not only to amass facts but also to create good citizens; but it should beware of exaggerating the importance of what is measurable, since some most significant things are not to be measured. Good science teaching should avoid the pitfalls of doctrinaire politics and ensure a sense of proportion and a balanced judgment, though these are not qualities gaining publicity in the more sensational newspapers. Sir Edward also said that the need in schools is to stress the fact that to live is more than livelihood, and that only by habitual zest in one's working hours can one ensure the zestful enjoyment of one's leisure. "To go slow in the one is the surest way of finding that time hangs heavy in the other". On the science teaching in schools there rests a great responsibility, but there are also the potentialities of a great achievement.

Each morning of the meeting began with two simultaneous lectures, those on the first morning being by Prof. L. J. Audus (Bedford College, London) on the attempts made during the Second World War by biologists in Japanese prisoner-of-war camps to stem the onset of deficiency diseases; and by Dr. C. C. Butler (Imperial College of Science and Technology, London) on the story of cosmic rays. The lectures on the second morning were by Prof. R. M. Barrer (Department of Physical Chemistry, Imperial College, London) on crystals as molecular sieves, and by Prof. F. A. Vick (Department of Physics, University College of North Staffordshire) on electrical aspects of contacts between solids. On the last morning lectures were given by Prof. R. J. Harrison (London Hospital Medical College) on recent research on whales and seals, illustrated by a film, and by Mr. H. W. Thorp (Department of Chemical Engineering, University College, London) on chemical engineering, which was also illustrated by films; a third lecture, later on the same morning, was by Mr. A. B. Soper (Cable and Wireless, Ltd.) on Commonwealth telecommunications.

Some of the most popular functions were the demonstrations and discussions. A lecture-demonstration on experiments with radioactive isotopes suitable for schools had to be repeated four times, the first version being attended by more than two hundred, who somehow got into a lecture theatre built for seventy; it was given by M. C. Nokes (Harrow), J. S. Strettan (Raynes Park Grammar School), T. A. H. Peacocke (St. John's School, Leatherhead), G. E. Perry (Kettering Grammar School) and W. G. Rhodes (Firth Park Grammar School, Sheffield). Another most popular demonstration was by K. A. Murch (Chichester High School for Boys) on ciné and ciné-micrography in the teaching of natural history.

A very valuable and provocative discussion, under the chairmanship of Mr. F. W. Kaye, was that on science in secondary modern schools—progress and prospects; it was initiated by A. E. J. Trinder (Alexandra Secondary Modern School, Bromley), and many members took part. The discussion on the last morning was on first-year failures in the universities, and for this Dr. H. F. Boulind (general secretary of the Association) was in the chair. It was introduced by Dr. E. R. Roberts (Department of Inorganic Chemistry, Imperial College) and by Prof. F. A. Vick. Representatives of the various colleges of the University of London had been invited to be present, and several spoke. It was generally agreed that the schools need to concentrate on trying to make pupils think, rather than on giving instruction for examinations, but how this is to be done was not so apparent. It is hoped that a tape-recording of the discussion may later be put into print. The third discussion was one by the Science and Religion Group of the Association, which was welcomed by the Rev. D. W. Cleverley Ford, vicar of Holy Trinity Church, Prince Consort Road, London, S.W.7. Many members spoke, and the proceedings ended with a gratifying increase in the numbers of the Group.

Evening functions included a lecture in the Courtauld Hall of Queen Elizabeth College by Mr. T. D. Bourdillon, on "Everest, 1953". Mr. Bourdillon, who was a member of the successful 1953 Everest Expedition, showed and explained the oxygen equipment and other gear which he used; his lecture was illustrated by most beautiful slides.

As usual, a main feature of the meeting was provided by the exhibitions of apparatus and books by manufacturers and publishers; these, together with the exhibition of teaching apparatus devised by members, were bigger than ever before, and strained the accommodation of the Royal College of Science to the utmost. The Home Office contributed a display of apparatus used in Civil Defence work by technical reconnaissance officers, and also lent a control set and 'walkie-talkies' so that officers of the Association could maintain contact with the secretary's office from any part of the College. Some sixteen firms were visited by members during the afternoons, as also were the High Pressure Laboratories of the Chemical Engineering Department at the Imperial College. In addition, on each afternoon scientific films were shown, some of which were introduced by Dr. J. A. Harrison (Educational Foundation for Visual Aids).

The meeting created a record for attendance, and the Association must count itself as singularly fortunate in this year's president, Sir Edward Salisbury, who insisted on sharing in all the activities; his zest showed that he was not content with precept in his address, but followed it with action during the meeting.

FARMING HISTORY IN GREAT BRITAIN

FARMERS, industrialists and scholars from all over Great Britain attended a joint meeting of the British Agricultural History Society and the Association of Agriculture, which was held in the University of London on December 3. Sir James Scott Watson, president of the History Society, took the chair, and three papers were read, one in the morning and two in the afternoon. This event, which is one of the two annual meetings convened by the Agricultural History Society, is usually open to non-members on payment of the conference fee.

The morning paper, read by Dr. H. Hamshaw Thomas, president of the History of Science Society, dealt with the life and writings of Richard Bradley, F.R.S., who lived in the early years of the eighteenth century. The paper gave much food for thought, for Bradley came very close to some of the most modern scientific discoveries. By a series of experiments he found that variegated leaf colours could be induced in healthy plants by grafting scions of discoloured plants. The variegation, which is really a virus disease, was, he found, transmitted through the circulation of the sap. Similarly, he was able to produce the breaking of tulip bulbs, which was forgotten or neglected until Sir Daniel Hall, all unknowingly, so it is thought, repeated Bradley's experimental work on modern lines. Besides his achievements in pure science, Bradley was a severely practical man. Through correspondents and personal observation he collected and recorded a great mass of information about the farm practice of his day. As Dr. Hamshaw Thomas said, a complete description of English farming methods of the early eighteenth century can be compiled from his work. Until the present day, Bradley has been regarded as somewhat of a charlatan, but Dr. Hamshaw Thomas's work has done much to retrieve his reputation.

After lunch the first paper was by Prof. Cyril Tyler, of the University of Reading, who dealt with the historical development of feeding standards for livestock, a subject that must be very close to the hearts of farmers in these times. Prof. Tyler ranged over the ages from classical times until the present day, describing the theories of the ancients and the slow progress that was made in gaining real knowledge of the subject until von Thaer's work in the early nineteenth century. It was unfortunate that von Thaer chose such a variable as good hay for his basic unit, but his work pointed the way. Many German and British chemists followed in his steps and, with slowly increasing knowledge, have to-day been able to lay down simple and practical rules for the breeder, dairy farmer and meat producer alike. It is a fascinating story and demonstrates, if that is necessary, that the findings of science are of universal application.

The third paper was rather more recondite and dealt with pollen analysis and its bearing on agricultural history, being given by Mr. J. W. Franks, of the Department of Botany, University College, Leicester. Mr. Franks demonstrated how what happened in districts now covered with peat or fen can be discovered by cutting down through the layers. The depth of the layers and other indications show how long they have taken to accumulate. In these layers of peat the pollen of the various flora that flourished is embedded and preserved, and by carefully collecting this pollen, identifying it and counting it, the flora of that particular age can be deduced. If man was living in the place when the pollen was deposited, his activities in growing cereal or other crops, or the effect of grazing animals, will be shown by the different pollens recovered.

All three papers dealt with subjects that were well worth while, and the conference was a great success. Those interested in this field should write to the Honorary Secretary, British Agricultural History Society, Mr. J. W. Y. Higgs, at the Museum of English Rural Life, 7 Shinfield Road, Reading.

GOVERNMENT RESPONSIBILITY IN INDUSTRIAL RESEARCH

THE extent and character of the responsibility taken by governments for research varies enormously. In the scientifically more advanced countries, the government attitude ranges from the benevolence combined with restricted actual participation to be found in Germany and the United States to the complete control of science exercised in the U.S.S.R. Even within the British Commonwealth, where there is a common tradition of government, the countries have developed different ways of reaching the level of research activity essential in a modern State. Some of the differences and the reasons for them were brought out in a discussion on "Government Responsibility in Industrial Research" held at the Society for Visiting Scientists on December 6 under the chairmanship of Sir Henry Tizard. The principal speakers were Dr. E. W. R. Steacie, president of the National Research Council of Canada, and Dr. B. K. Blount, deputy secretary of the Department of Scientific and Industrial Research, and there were contributions from a number of Commonwealth countries and the United States.

Dr. Steacie said that the structure of research in Canada differs markedly from that in Britain or the United States. As a pioneer country, the primary industries developed first, and long before there was a National Research Council research organizations were set up in government departments to deal with their problems. In the initial stages the Canadian secondary industries were mostly branches or subsidiaries of firms in the United States or in Britain, and any research was done by the parent company. This has resulted in a very minor amount of research being done by industry, and a correspondingly greater proportion having to be done by the government for industry.

The National Research Council, charged mainly though not exclusively with the responsibility for industrial research, was set up in 1916 by the Canadian Government at the suggestion of the British Government. At that time there was little secondary industry in Canada, and most of the plants established to meet the needs of the First World War disappeared at its end. It was not until the Second World War that major development of secondary industry took place. In some ways development in Canada has paralleled that in the United States, but "one war behind". In the latter, industrial expansion took place in a period when research by industry was developing in the world generally, but Canadian expansion is happening at a time when there is already a great deal of research abroad. Canada has never gone through a period when there was a large body of research in industry. While there is now a tendency even for subsidiary companies to set up research organizations, the major responsibility for keeping Canada abreast of the times through research falls on government organizations.

It is always difficult to get accurate figures for research expenditures; but the amount allocated in 1954 by the Canadian Government for research in the primary and secondary industries and health was about 43,000,000 dollars, excluding military and atomic energy research; this does not include expenditures by either Provincial authorities or universities. No exactly comparable figures are available; but roughly the Canadian Government is spending twice as much per capita on civil research as the United States Government. On the industrial side, however, the contribution is extremely small. The figures are very unreliable; but they do support the thesis that what is wanted in Canada is a large increase in research in industry rather than by government.

Dr. Steacie went on to describe the organization of research in Canada and the ways in which assistance is rendered to industry. The Department of Agriculture operates large research and demonstration establishments with an annual expenditure of about 17,000,000 dollars. The mining industry is served by the Department of Mines and Technical Surveys, and the ore-dressing laboratory of this Department is particularly noteworthy because the free service which it gives in investigating suitable methods of treatment for the ores from new mines has done so much to aid the development of Canadian resources. The National Research Council, on its own initiative, undertakes long-term research for secondary industry and undertakes shorter-term research under contract for individual firms or groups. The proportion of the expense borne by the industry varies with the circumstances. The research councils of the Provinces work mainly on the shorter-term problems of local industry, sometimes on contract, and in some respects fill the place taken by the large specialized consulting firms and sponsored research in the United States. Research associations, so successful in Britain, are practically non-existent in Canada, partly because of the high proportion of subsidiary firms and partly because of the scattered distribution of industry. Only the pulp and paper industry operates its own co-operative laboratories.

Canada, like every other country, is faced with the problem of getting technical information into the hands of industry. The needs of primary industry are looked after by the appropriate government departments. For secondary industry, lacking research associations as a channel for disseminating information, the Research Council has set up a Technical Information Service which works closely with the Provincial research councils and other bodies in active measures to bring the benefits of new and existing technical information to industry.

Dr. Blount contrasted the Canadian and British conditions, pointing out that Canada is a country with large resources and capable of feeding itself, and that industry in Britain is long established compared with Canada, with a high proportion of craft industry where the best techniques have been found by trial and error over a long period. Even in such industries, however, the need for research is growing because of changing conditions, particularly with regard to raw materials and the need for increased scientific control with the gradual disappearance of the traditional craftsman. The small size of most of the firms gives the opportunity for real help through research associations.

While the figures are not very reliable, the total expenditure on research of all kinds in Britain is probably about £300,000,000, or about one-fifth of the corresponding figure for the United States. It is almost impossible to estimate the government expenditure on research applicable in civil industry, since much of this is included in the budgets of the Armed Services. It is fairly certain, however, that the expenditure by industry is at least equal to that by government, in contrast to the Canadian situation.

After Dr. Blount's talk there were many contributions to the discussion, including a notable one by the chairman himself; but in general three topics were considered: research in India, the difficulty of assessing research effort, and research associations. In India, as in Canada, attention was first given in the past to the primary industries, namely, agriculture and forestry. Now, industrial research is increasing in importance, the expenditure having risen from £50,000 in 1940 to about £900,000. Government research will probably always be dominant in India because of the creation of State industries.

The need for more reliable figures on research expenditures was stressed, particularly as a guide for the distribution of effort in view of the great cost of development and full-scale exploitation as compared with research. Several speakers referred to the value of studying the man-power rather than expenditure, especially in attempting to compare the situations in different countries.

Research associations have been successful in New Zealand where there is a preponderance of small industries; but in Australia they are few in number and indifferently successful. In the United States the place of research associations is taken by the large institutions undertaking sponsored research. Several speakers told of the interest of large firms, and were of the opinion that the smaller firms which the research associations are particularly designed to help are often "poor members". There was general agreement that the best place to do industrial research is in industry and that, ideally, government and co-operative efforts should cover those fields not adapted to research by individual firms.

AFRICAN HONEY-GUIDES

AMONG the strangest forms of animal behaviour is that of the honey-guides, African birds distantly related to the American woodpeckers, which 'guide' men, baboons and ratels (honey-badgers) to the nests of wild honeybees—supposedly so that these nests can be broken open.

A study of the behaviour is described by Dr. Herbert Friedmann, U.S. National Museum curator of birds, in a bulletin issued by the Smithsonian Institution, Washington. Dr. Friedmann has observed at least twenty-three instances of the habit and has collected other well-authenticated data from African associates.

Dr. Friedmann describes the behaviour as follows : "When the bird is ready to begin guiding, it either comes to a person and starts a repetitive series of churring notes or it stays where it begins calling these notes and waits for the human to approach it more closely. If the bird comes to the person to start leading him, it flies within 15 or 20 feet from him, calling constantly and fanning its tail. If it waits for the potential follower to approach it for the trip to begin, it usually perches on a fairly conspicuous branch, churring rapidly, fanning its tail, and slightly arching and ruffling its wings so that at times its yellow shoulder bands are visible.

"As the person comes to within 15 to 50 feet from it, the bird flies off with an initial conspicuous downward dip, and then goes off to another tree, not necessarily in sight of the follower ; it is more often out of sight than not. It waits there, churring loudly until the follower again nears it, when the action is repeated. This goes on until the vicinity of the bees' nest is reached. Here the bird suddenly ceases calling and perches quietly in a tree nearby. It waits there for the follower to open the hive and usually remains until the person has departed with a collection of honeycomb, when it comes down to the plundered bees' nest and begins to feed on the bits of comb left strewn about. The time during which the bird may wait quietly may vary from a few minutes to well over an hour and a half."

African natives regard the bird as an almost infallible guide to honey. They try to attract it by grunting like a ratel or chopping on trees to imitate the sound of opening a nest. Dr. Friedmann suggests that the habit is purely on an instinctive level and is not a deliberately associative act. It presumably originated before the advent of human beings, perhaps starting with the ratel, that still co-operates with the bird, and whose place in the association the African natives have deliberately tried to take. The honey-guide does not seem interested in the honey *per se*, or in the grubs of bees found in the nests. It has an insatiable appetite for the beeswax, which it will take wherever it can be found. With various collaborators, Dr. Friedmann is now carrying out an intensive study of the mechanism of wax digestion.

THE NATIONAL TRUST

ANNUAL REPORT

THE sixtieth annual report of the National Trust, presented to the annual general meeting in Manchester on November 24—the first to be held out of London—records that there are now a hundred and twenty historic houses in the care of the Trust, which owns more than 220,000 acres and has a membership of more than fifty thousand, compared with a membership of seven thousand in 1945 when the Trust had sixty-three houses and owned 107,000 acres, and in 1914 a membership of 725, 5,500 acres and a handful of historic houses. The National Trust Act of 1937 specifically extended the purposes of the Trust to include the preservation of furniture, pictures and other works of art, and since that date the Trust has become responsible for many important collections associated with the country houses under its care. Its responsibility for works of art is likely to increase since the Finance Act of 1953 empowered the Treasury to accept, in payment of death duties, chattels associated with historic houses in the ownership of the Trust. The annual report gives some account of the work of the Trust in this field, and at the annual general meeting Prof. A. B. Blunt, surveyor of the Queen's pictures and director of the Courtauld Institute, who has for some years been the Trust's honorary adviser on paintings, also described some of the maintenance problems that arise.

The report emphasizes that the Trust does not regard its primary duty, in respect of its farmlands and the preservation of the unspoilt landscape committed to its care, as in any way conflicting with the interests of good farming, and the policy of modernizing the farms continues steadily. Deeds of dedication have now been completed with the Forestry Commission in respect of some 4,699 acres of the Trust's 30,000 acres of woodland, including 1,095 acres at Clumber, where, with the release by the Army of 850 acres, the whole property is now open to the public. For the first time since 1947, the accounts show a small surplus (£979) on the maintenance and administration of the Trust's general properties ; but, although the income from annual subscriptions increased by some £5,000, legacies and donations are at present decreasing annually, and a large increase in membership is essential if the Trust is to do no more than watch over a fraction of the property requiring its care.

The Trust aims at a membership of seventy thousand before the end of 1956, and, in stressing the urgent need for such an increase, Lord Chorley warned the annual general meeting of the great danger of complacency. The danger to the great country houses is more acute than ever, and at present the Trust can only accept such houses if an endowment for all time is offered with the house. Lord Derby, who also addressed the meeting, stressed the voluntary standing of the Trust and made it clear that the Trust depends on private support and not on national contributions. He said that he was impressed by the small amount of litter left by the public when they visit Knowsley, in contrast with the amount left at many of the Trust's properties where admission is free. Reference was also made at the annual meeting to the launching of a scheme of corporate membership, by which it is hoped to enrol organizations such as industrial firms.

SYNTHESIS AND BLEACHING OF RHODOPSIN

By Dr. GEORGE WALD and PAUL K. BROWN
Biological Laboratories, Harvard University

THE purpose of this communication is to demonstrate in two exemplary experiments certain basic relationships among the principal components of the rhodopsin system.

Rhodopsin is synthesized in solution by incubating together in the dark neo-*b* (7-*cis*) retinene[1] and the rod protein, opsin. It bleaches in the light to a mixture of all-*trans* retinene and opsin[2]. This sequence of reactions is recorded in Fig. 1.

The synthesis of rhodopsin is shown at the left. A solution of cattle opsin in 2 per cent aqueous digitonin was used as blank; the spectrum of opsin, or of the opsin moiety of rhodopsin, is therefore excluded from the record. The same concentration of opsin was mixed with neo-*b* retinene in 2 per cent digitonin, and the spectrum recorded at once in a Cary spectrophotometer (curve 1). Although completed within 20 sec. after mixing, this spectrum already displayed a hump at about 500 mμ owing to the formation of a trace of rhodopsin. Spectra were recorded periodically thereafter in the dark, at the times shown in the legend of the figure. (The light involved in the spectrophotometry is too weak to bleach rhodopsin or to retard its synthesis appreciably.) The concentration of rhodopsin ($\lambda_{max.}$ 498 mμ) rose regularly, while that of neo-*b* retinene ($\lambda_{max.}$ 380 mμ) fell. The reaction was complete in about two hours. The small absorption band at about 350 mμ remaining in the final product (curves 8 and 9) is due primarily to the β-band of rhodopsin[3]. When opsin is in excess, as here, the synthesis of rhodopsin removes neo-*b* retinene almost entirely from solution.

The rhodopsin synthesized at the left of Fig. 1 is bleached at the right. Curve 9 is re-drawn at the right as curve 1. The solution was exposed for measured intervals to the orange light of a 160-W. microscope lamp passing through a Jena *OG*2 filter, which transmits all wave-lengths longer than 550 mμ. This region of the spectrum, though it bleaches rhodopsin, is not absorbed by, and so does not isomerize, the retinene formed as product[2]. Immediately following each exposure, the absorption spectrum was recorded in the dark. After a total irradiation of 180 sec. (curve 6), the solution was exposed for 45 sec. to the same source passing through a Corning 3387 filter, which transmits all wave-lengths longer than about 440 mμ (curve 7).

As the irradiation progressed, the rhodopsin maximum fell regularly, and the retinene maximum rose. By curve 7, the solution had been bleached completely, and again contained nothing but retinene and opsin. The retinene formed by bleaching rhodopsin, however, is not the same as enters its synthesis. In such non-isomerizing lights as here employed, the product of bleaching is primarily all-*trans* retinene[2]. This possesses a much larger specific extinction than neo-*b* retinene. Fig. 1 (right) suggests that we had finished with much more retinene than we began; but what in fact happened is that this sequence of reactions isomerized the initial neo-*b* to all-*trans* retinene.

One can regard such a cycle of synthesis and bleaching of rhodopsin as an enzymatic isomerization, catalysed by opsin. In this sense, opsin acts as an isomerase activated by light—a photoisomerase. Neo-*b* retinene is its substrate, and rhodopsin the light-sensitive enzyme-substrate complex.

Fig. 1 contains further internal evidence that the pathway of rhodopsin synthesis differs from that of bleaching. The absorption spectra at the left display a sharp common or isosbestic point at about 422 mμ,

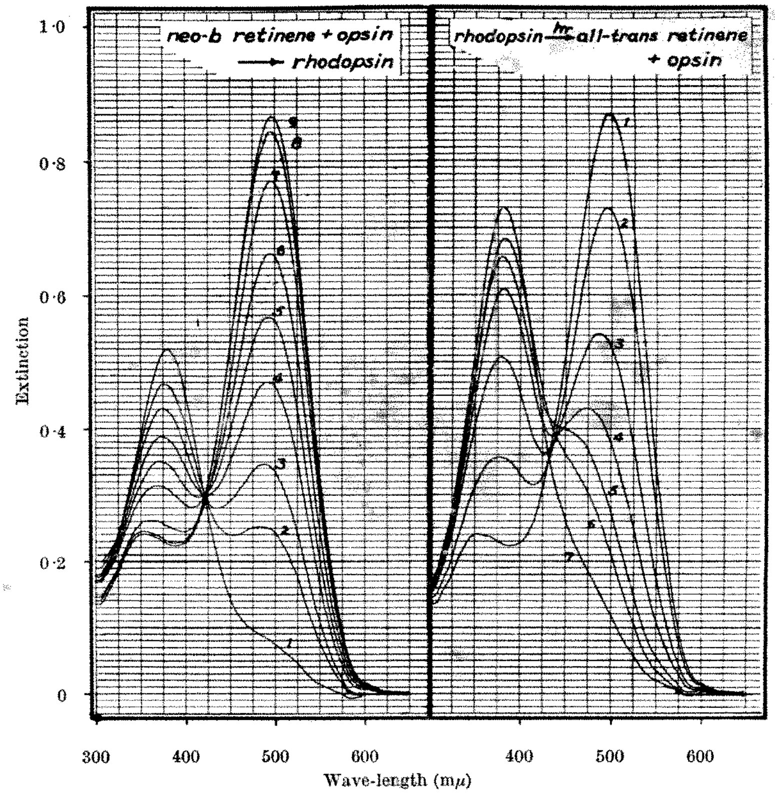

Fig. 1. Synthesis and bleaching of rhodopsin in solution (22·5° C., *p*H 7·0). Left, a mixture of neo-*b* retinene and cattle opsin incubated in the dark, and absorption spectra recorded periodically: (1) at 0·3 min., (2) at 2·5, (3) 5, (4) 10, (5) 18, (6) 30, (7) 60, (8) 120, and (9) at 180 min. The absorption band of neo-*b* retinene (λmax. 380 mμ) falls regularly, whereas that of rhodopsin (λmax. 498 mμ) rises. Right, the rhodopsin formed at the left (1) is exposed to light of wave-length >550 mμ for various intervals, and spectra recorded immediately. The total irradiations are (2) 5 sec., (3) 10, (4) 15, (5) 30, and (6) 120 sec. The residue was exposed for 45 sec. longer to light of wave-length >440 mμ (7)

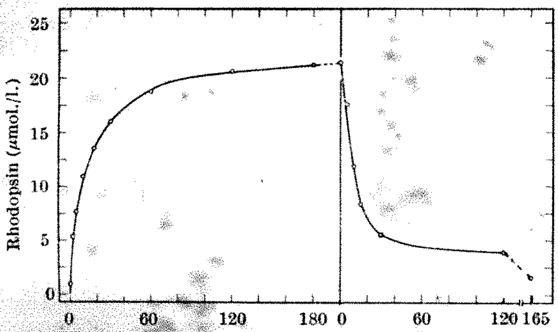

Fig. 2. Kinetics of synthesis and bleaching of rhodopsin, from the data of Fig. 1. Left, synthesis: the points are experimental, the line the theoretical curve for a bimolecular reaction. Right, bleaching: the points are experimental, and an arbitrary line is drawn through them

an indication that only two molecular species—neo-*b* retinene and rhodopsin—are involved in the recording. The curves at the right have no such common point. Bleaching is known to be a more complex process than the over-all equation above these curves expresses. It involves the orange intermediates, lumi- and meta-rhodopsin[4], and the final formation of new complexes between opsin and all-*trans* retinene (see below).

We have spoken of the absorption bands in the ultra-violet as those of neo-*b* and all-*trans* retinene. This is not quite correct. In such solutions, retinene condenses rapidly with amino-groups of opsin and other substances to form Schiff bases which behave as *p*H indicators[5]. These vary in $\lambda_{\text{max.}}$ from about 366 mμ at *p*H 9 to about 390 mμ at *p*H 5, and at all *p*H's involve some distortion of the retinene spectrum.

If this factor is momentarily disregarded, we have as molar extinctions in digitonin solution: rhodopsin, 40,600[6]; all-*trans* retinene, 38,300[6]; and neo-*b* retinene, 21,200[6,7]. Therefore we expect that, as neo-*b* retinene forms rhodopsin, $E_{\text{max.}}$ should rise $40{,}600/21{,}200 = 1\cdot9$ times; in Fig. 1 (left) it rises 1·7 times. We expect that as rhodopsin bleaches to all-*trans* retinene, $E_{\text{max.}}$ should fall $38{,}300/40{,}600 = 0\cdot92$ times; in Fig. 1 (right) it falls 0·84 times. These discrepancies are small but cumulative: the isomerization of neo-*b* to all-*trans* retinene should raise $E_{\text{max.}}$ $38{,}300/21{,}200 = 1\cdot8$ times. In Fig. 1 the final retinene maximum at the right is 1·4 times higher than the initial retinene maximum at the left. The over-all yield of the reaction, regarded as an isomerization, appears therefore to be low. One reason for this may be the distortions of retinene spectra by proteins, mentioned above. Another undoubtedly is some degree of isomerization, unavoidable in the course of bleaching. Even such orange lights as used in the present experiment, though not efficiently absorbed by retinene, are absorbed by, and isomerize to some degree, lumi- and meta-rhodopsin[2]. As a result, the product of bleaching always contains small amounts of geometrical isomers other than all-*trans* retinene.

The synthesis of rhodopsin in solution from neo-*b* retinene and opsin follows the course of a second-order (bimolecular) reaction[2]. In the present instance, the initial concentration of opsin, determined in a separate experiment by incubating with excess neo-*b* retinene and measuring the rhodopsin formed, is 28·96 μmoles per litre; and of neo-*b* retinene, 21·35 μmoles per litre. The extinctions of rhodopsin in Fig. 1 (left) are computed from the simultaneous equations:

$$x = E_{500} - 0\cdot069\,y\,; \quad \text{and } y = \frac{3\cdot77\,E_{375} - E_{500}}{3\cdot70}$$

in which E_{375} and E_{500} are the extinctions at 375 and 500 mμ; *y* is the extinction at 375 mμ specifically due to neo-*b* retinene, and *x* the extinction at 500 mμ specifically due to rhodopsin. The latter quantity, divided by 0·0406, yields the concentration of rhodopsin in μmoles per litre.

This has been plotted in Fig. 2 (left). The line which accompanies these points is computed from the equation for a bimolecular reaction:

$$kt = \frac{2\cdot303}{a-b}\log_{10}\frac{b(a-x)}{a(b-x)}$$

in which *k* is the rate constant, *t* the time in minutes, *a* and *b* are the initial concentrations of opsin and neo-*b* retinene, and *x* is the concentration of rhodopsin. In the present experiment (22·5° C., *p*H 7·0), *k* has the value 0·0026 litre per μmole per min. (4·33 litres per mole per sec.).

The bleaching of rhodopsin is first-order, provided that the light reaction is limiting, that is, that the 'dark' reactions which remove lumi- and meta-rhodopsin are complete at all stages of bleaching. This condition is not fulfilled in the present experiment. The kinetics of bleaching therefore cannot be treated precisely in this instance. The concentrations of rhodopsin have been estimated from the spectra of Fig. 1 (right) by using simultaneous equations like those above, but differing somewhat in numerical coefficients since all-*trans* retinene replaces neo-*b* retinene in the bleaching mixtures. The points so obtained are plotted in Fig. 2 (right), and an arbitrary line is drawn through them.

The data of bleaching in Figs. 1 and 2 (right) reveal a further complexity. Curves 1–6 in Fig. 1 (right), and also the corresponding points in Fig. 2, form a regular sequence which describes the bleaching of rhodopsin in light of relatively long wave-lengths (> 550 mμ). The final exposure (curves 6–7) involves two important changes: a large increase in the intensity of the light; and the inclusion of much shorter wave-lengths (> 440 mμ). The first change

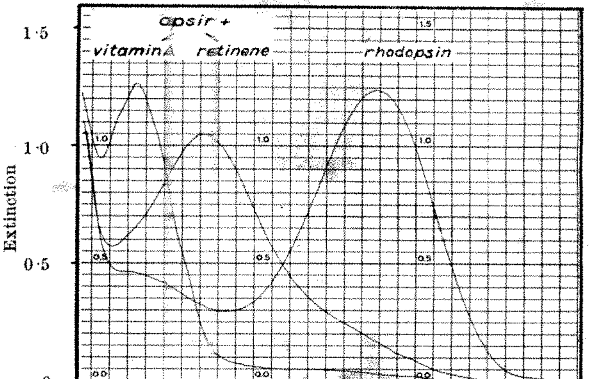

Fig. 3. The bleaching of rhodopsin in solution (23° C., *p*H 7·0). A solution of cattle rhodopsin (λmax. 498 mμ) was bleached in orange light to a mixture of all-*trans* retinene and opsin (λmax. 383 mμ). On adding potassium borohydride, the retinene was reduced to all-*trans* vitamin A (λmax. 325 mμ)

increases the rate of bleaching, the second its character. Whereas the bleaching from curves 1 to 6 involves a maximum fall of extinction at 503 mμ, that from curves 6 to 7 is maximal at a much lower wave-length, 474 mμ. The initial exposure to light of wave-lengths greater than 550 mμ, while bleaching rhodopsin, had permitted the formation of artefacts which absorb at lower wave-lengths: some *iso*-rhodopsin ($\lambda_{\max.}$ 487 mμ)[2], and an orange-yellow, light-sensitive pigment with $\lambda_{\max.}$ about 440 mμ. The latter is formed in small amounts when retinene is incubated with a number of proteins, including opsin and egg albumin, either in the dark or in lights of sufficiently long wave-length to spare it. Small amounts of this artefact form in the course of every bleaching of rhodopsin in orange or red light.

In the retina, the retinene formed by bleaching rhodopsin ordinarily is reduced to vitamin A. This is accomplished by the enzyme, alcohol dehydrogenase, working together with reduced cozymase (DPN–H)[8]:

$$\underset{\text{retinene}}{C_{19}H_{27}CHO} + DPN{-}H + H^{+} \overset{\substack{\text{alcohol}\\ \text{dehydrogenase}}}{\rightleftharpoons} \underset{\text{vitamin A}}{C_{19}H_{27}CH_2OH} + DPN^{+}$$

This reduction can be carried out conveniently in solution with potassium borohydride. A solution of cattle rhodopsin was bleached in a non-isomerizing orange light to a mixture of all-*trans* retinene and opsin (Fig. 3). (In measuring these spectra, digitonin solution served as blank; hence the rising absorption below 310 mμ owing to opsin. In Fig. 1 opsin was in the blank, and its absorption therefore did not appear.) On adding a droplet of potassium borohydride solution in water to the bleached product, the retinene was immediately reduced to vitamin A ($\lambda_{\max.}$ 325 mμ). The molar extinction of all-*trans* vitamin A in aqueous digitonin is about 45,600. Therefore in going from retinene to vitamin A, $E_{\max.}$ is expected to rise 45,600/38,300 = 1·19 times. In Fig. 3, it rises 1·20 times. This simple procedure therefore completes in solution and quantitatively the sequence of reactions by which rhodopsin bleaches.

The final spectrum in Fig. 3 includes a very small 'tail' of absorption, maximal near 450 mμ. This is the artefact already mentioned, formed whenever rhodopsin is bleached in orange or red light.

This investigation was supported in part by grants from the Rockefeller Foundation and the Office of Naval Research. [July 27

EVIDENCE FOR A REVERSIBLE FIRST-ORDER PHASE TRANSITION IN COLLAGEN–DILUENT MIXTURES

By R. R. GARRETT and Prof. P. J. FLORY

Chemistry Department, Cornell University, Ithaca, N.Y.

THE view that thermal shrinkage in collagen is primarily a process of melting, though not widely accepted, is nevertheless supported by a variety of observations[1]. Transition from a predominantly crystalline to an amorphous state is indicated by the X-ray diffraction work of Astbury[2]. An increase in volume on shrinkage of water-swollen collagen has been reported by Weir[3] and in heat content by Küntzel and Doehner[4] and by Wöhlisch and de Rochemont[5]. Theis[6], Lennox[7], and others have observed that the temperature of the transition is lowered systematically by dilution. The shrinkage process has been variously described, however, as a degradation (or hydrolysis) to gelatin, or as a 'denaturation process' similar to the phenomenon of protein coagulation[8] rather than as a true phase transition. In this communication we report observations on the volume changes occurring during thermal shrinkage and recrystallization of collagen, which in our opinion offer convincing evidence of a phase transition appropriately characterized by a melting point.

Collagen was prepared from beef tendo achillis which had been extracted to remove globular proteins, fats, and certain of the mucopolysaccharides. After having been cut into sections 0·01 in. in thickness, it was dried to constant weight, and portions were swollen in ethylene glycol vapour to the desired concentrations by weight. 7- to 20-gm. samples were introduced into dilatometers of 0·50 mm. capillary radius, which were then sealed, evacuated, and filled with mercury as a confining liquid.

The filled dilatometers were heated rapidly to a temperature within three or four degrees of the transition temperature, T_m, after which the heating rate was reduced to three degrees per day. Equilibration was rapid above T_m. The liquidus was therefore established in a comparatively brief period, transformation to gelatin thus being avoided. Less than 5 per cent water-leachable material was found on removal of the sample from the dilatometer, indicating negligible formation of gelatin during the melting process.

The volume–temperature curves were found to resemble those for the melting of many crystalline copolymers and to exhibit a similarly broad melting range[9–12]. A typical plot is shown in Fig. 1 for the composition having a weight fraction of collagen, $w_2 = 0{\cdot}700$. The ordinate, Δy, represents the difference between the dilatometer scale reading observed for the melted sample (or calculated for that temperature assuming a linear liquidus) and the scale reading observed for the partly crystalline sample. The point at which Δy reaches zero, and hence at which melting is complete, should correspond to the melting point, in accordance with interpretations established for other polymer systems[13,14]. The 'rounding off' of the curve (Fig. 1) in this region is suggestive of copolymer melting[15].

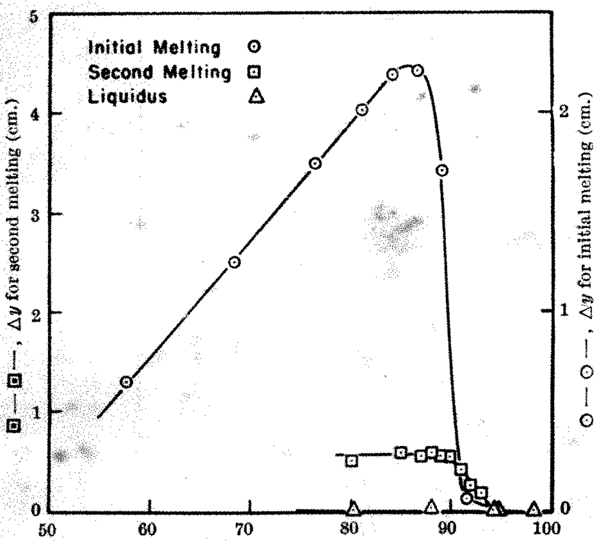

Fig. 1

When the more dilute samples were supercooled some fifteen to forty degrees below T_m, a slow recrystallization proceeded over a period of one or two days as evidenced by a small but unmistakable volume decrease of the order of magnitude of 10^{-4} c.c./gm. of collagen. Upon subsequent heating, re-melting occurred at the same temperature, T_m, observed initially, or at most a few degrees below it. Small discrepancies, when observed, are attributable to the formation at low recrystallization temperatures of crystallites which are less perfect than those existing in native collagen and hence melt at a lower temperature. Similar behaviour is commonly observed in other polymeric substances[16].

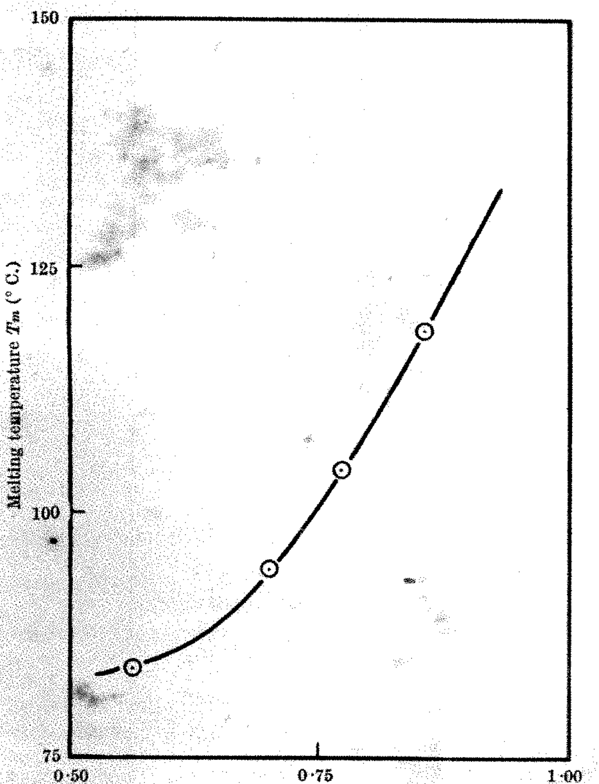

Fig. 2

An extrapolation of the curve shown in Fig. 2 to $w_2 = 1$ yields a value of about 145° C. for $T°_m$, the melting temperature of unswollen collagen. The heat, ΔH, and entropy, ΔS, of fusion of crystalline collagen may be calculated from the melting point depression by glycol, using procedures which have been successfully applied to phase transitions in other crystalline polymers[13,14,17]. The values so obtained are, respectively, 24 cal./gm. and 0·055 cal./deg./gm., where the density of collagen was taken to be 1·35 gm./c.c. The corresponding molar quantities per structural unit derived from the average molecular weight of the collagen structural unit of 94 gm./mole, are 2,200 calories and 5·3 cal./deg. The former appears to be somewhat less than the value to be expected for the dissolution of one hydrogen bond per residue.

The number of bonds freed by melting to assume random rotational configurations may reasonably be estimated as two per residue. The entropy change per bond thus becomes 2·6 cal./deg./bond, a value somewhat higher than that observed for most other polymers. Such a value for the entropy indicates that a high degree of order exists in the crystalline regions and that the collagen molecule assumes a random configuration in the liquid state.

The volume-temperature behaviour of collagen thus exhibits the features characteristic of crystal-liquid transitions in other polymeric substances: a well-defined melting temperature which is determined only by the composition of the collagen-diluent mixture and is independent of the previous thermal history of the sample; a time-dependent recrystallization, suggesting the necessity for some sort of re-nucleation to precede crystalline growth, as has been found for polymers generally; and the virtual recovery after recrystallization of the initial melting temperature. The conformity of collagen to these criteria characterizing a phase transition suggests the further application to collagen and other fibrous proteins of methods previously applied successfully to the study of polymer crystallization.

This work was carried out at Cornell University as part of a research programme supported by the Allegany Ballistics Laboratory, Cumberland, Md., an establishment owned by the United States Navy and operated by the Hercules Powder Co. under Contract *NOrd* **10431**. [Sept. 27

Absorption of 3·5-m. Radiation in the Optical Emission Nebula, *NGC* 6357

In the course of a radio survey of bright emission nebulæ with the 1,500-ft. Sydney cross-aerial, some fourteen nebulæ were studied at a wave-length of 3·5 m. Six were probably observed in emission, seven were undetectable, and one, *NGC* 6357, was observed in absorption. The observation of *NGC* 6357 is the first reported case of absorption of radio waves by an emission nebula; it leads to an estimate of the electron temperature of the nebula based almost entirely on radio data. In this preliminary communication the observation and its consequences are discussed briefly; a more complete account of the survey will be given elsewhere.

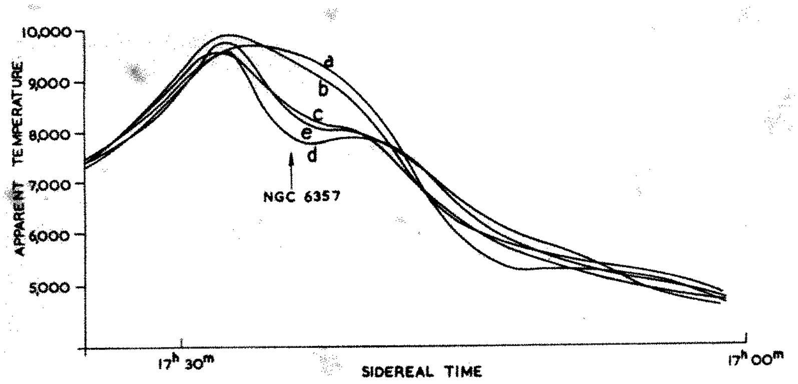

Fig. 1. Tracings of records obtained at five declinations superimposed to display the absorption effect at the position of *NGC* 6357. Declinations: (*a*) − 35° 11′; (*b*) − 34° 51′; (*c*) − 34° 31′; (*d*) − 34° 11′; (*e*) − 33° 51′

The radio telescope has a pencil-beam response, 50′ between half-power points, and is used as a transit instrument. It may be used to scan through a small angle in the meridian plane, recording five separate declinations quasi-simultaneously. In Fig. 1 are shown tracings of five such records straddling the nebula position and superimposed to display the effects of absorption. The position of the nebula is 17h. 18·4m., − 34° 03′ (1900), and the angular size is 63′ × 43′ [1]. Maximum absorption is estimated to occur at a position of 17h. 18·7m. ± 0·2m., − 34° 05′ ± 5′ (1900), in good agreement with the nebula position and in even better agreement with a radio measurement at 9·4 cm. by Haddock, Mayer and Sloanaker[2].

It is easily seen that the electron temperature of a mass of ionized gas observed in absorption must normally be less than the apparent brightness temperature at its centre (if both the nebula and background are irregular, with comparable scale factors, this is not necessarily true, but it appears safe to ignore such a possibility here). The brightness temperature at the nebula position is 7,800° K., with an estimated maximum calibration error of ± 20 per cent, or 1,600 deg. K. Thus the electron temperature of the nebula is probably less than 7,800° K. and almost certainly less than 9,400° K. An estimate of the actual temperature may be made if some other properties of the nebula and the galactic radio emission are known. It can be shown that if absorption between the nebula and observer is negligible, the electron temperature T_e is given by the equation:

$$T_e = T_a - (T - T_a)\left\{\frac{\Omega_0}{\Omega_n(1 - \varepsilon^{-\tau})} - 1\right\} - \alpha D$$

where T_a is the apparent brightness temperature measured at the nebula position; T is the brightness temperature in the absence of the nebula, estimated by interpolation; Ω_0 is the equivalent solid angle of the nebula after smoothing with the aerial beam; Ω_n is the actual solid angle and τ the optical depth (assumed uniform) of the nebula; α is the apparent brightness temperature of the galactic radio emission per unit distance in the direction of the nebula, and D is the distance to the nebula.

We take the following values: $T_a = 7{,}800°$ K.; $T = 8{,}800°$ K.; $\Omega_n = 1{\cdot}9 \times 10^{-4}$ steradian (corresponding to a size of 63′ × 43′); $\Omega_0 = 3{\cdot}6 \times 10^{-4}$ steradian (obtained by smoothing Ω_n with the aerial beam); $\varepsilon^{-\tau} \approx 0$ (consistent with the measurements of flux density at 9·4 cm.); $\alpha \approx 0{\cdot}5$ deg. K./parsec (estimated from the integrated brightness through the galaxy); $D = 1{,}000$ parsecs (distance of the assumed exciting star, − 34° 11671).

The corresponding electron temperature is 6,500° K., which is of the same order as, but rather lower than, 10,000° K., the temperature usually assumed for such nebulæ; the value could be even lower if the nebula were 'patchy'. A quantitative optical study of the nebula might prove very interesting.

Frequency Variations in New Zealand of 16 kc./s. Transmissions from *GBR* Rugby

We have made comparisons of the received frequency of the British Post Office Station at Rugby (*GBR*), distant 19,000 km., with the frequency of one of our standard crystal oscillators, following the receipt of information[1] that *GBR* is controlled by the British Standard Frequency source.

Equipment for this purpose consists of a narrow-band tuned amplifier on 16 kc./s. followed by a mixer to which is also fed a large 16 kc./s. signal derived from one of our oscillators. Any beat frequency present in the mixer output is recorded continuously on a paper chart. For convenience, our oscillator is adjusted to be about 3 parts in 10^7 fast; thus the beat frequency recorded is about 17 c./hr.

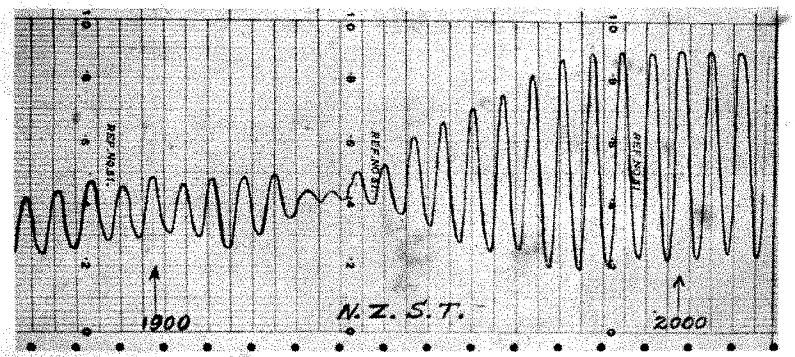

Fig. 1

Since the ratio of mean signal to peak noise of *GBR* at the receiving site is approximately − 20 db. for a bandwidth of 400 c./s., the beat frequency is passed through a low-pass filter with a cut-off frequency of 0·01 c./s. before being applied to the recorder, so that a high signal/noise ratio is maintained on the chart.

A sample record is shown in Fig. 1. It shows the beat frequency between *GBR* and our standard, the amplitude of the record being proportional to the amplitude of the signal received from *GBR*. The relative variations in frequency are derived from the number of cycles occurring in a given time. It is possible to determine the frequency of *GBR* in terms of the frequency of our own oscillator to within about one part in 10^9 in a 1-hr. period. However, our oscillator at times shows frequency variations greater than this.

Fig. 2 is a plot of the apparent frequency variations of *GBR* against our oscillator for the day on which the record of Fig. 1 was obtained, together with a plot of relative amplitude of the signal. On another day the received frequency about 1800 G.M.T. was observed first to increase above, and then decrease below, the mean frequency, although the magnitude of frequency shift was similar. At present the received frequency of *GBR* appears to be constant within the accuracy of measurement (4 parts in 10^9) over the periods 0900–1700 G.M.T. and 2100–0600 G.M.T.; but around 1900 and 0730 G.M.T.—the times at which the amplitude of the signal from *GBR* goes through its minima—there are marked changes in frequency of the order of 2 parts in 10^8. The portion of chart reproduced in Fig. 1 covers one of these periods. The accuracy of measurement in the steady periods may be limited by the short-term stability of our own oscillator rather than by the instability of the transmission path. The frequency of *WWVH* as received and measured at the same site[2] shows variations at least one order greater than those of *GBR*, both diurnally and over short periods.

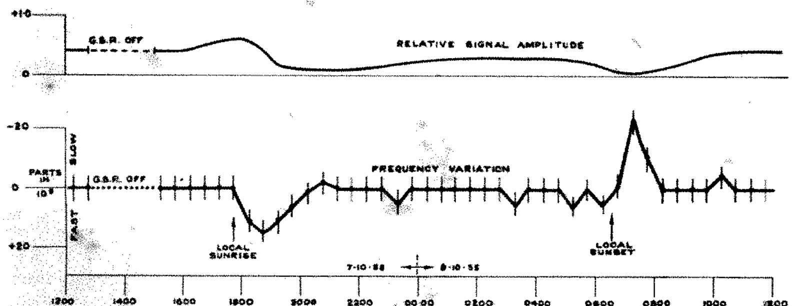

Fig. 2

Pierce, Mitchell and Essen suggest[1] the possibility of a world-wide basis for frequency comparison. We feel that our results are evidence for this possibility, and we hope to carry out long-term observations of *GBR* to that end, providing that the frequency control of *GBR* continues as at present.

We acknowledge the encouragement given to this work by Mr. W. H. Ward and the assistance of Mr. F. Ellis in instrumentation.

Production of Self-Reversal of Thermo-remanent Magnetism by Heat Treatment of Ferromagnetic Minerals

IT has been already reported by us[1] that the reverse thermo-remanent magnetism of the Haruna rocks is due to magnetic interaction between two different constituents of very small size in ferromagnetic mineral grains, which are mainly composed of ilmenite–hæmatite solid solutions. The production of reverse thermo-remanent magnetization of the Haruna and the similar rocks can be intensified by suitable heat treatment of the samples. This is illustrated in the upper and middle diagrams in Fig. 1.

The samples examined here are the ferromagnetic minerals separated out from the Haruna rock (upper diagram) and the Sokota rock (middle diagram). Both these minerals are mainly ilmenite and hæmatite solid solutions, the Curie points of which range from 100° C. to 320° C. When these samples are kept for a time at about 680° C. in the atmosphere and then quenched to room temperature, their reverse thermo-remanent magnetism becomes markedly increased. In Fig. 1, the abscissa shows various temperatures at which the heat treatments were carried out and the ordinates the intensity of total thermo-remanent magnetism that was acquired by cooling from 400° C. in the geomagnetic field after the heat treatment. The full lines in these diagrams represent the result of the heat treatment during 10 min. at the respective temperatures, while the broken lines show the final result of the same heat treatment maintained for a sufficiently long time. It is clear that the heat treatment at about 680° C. is most effective for intensifying the reverse thermo-remanent magnetism, and that these samples become

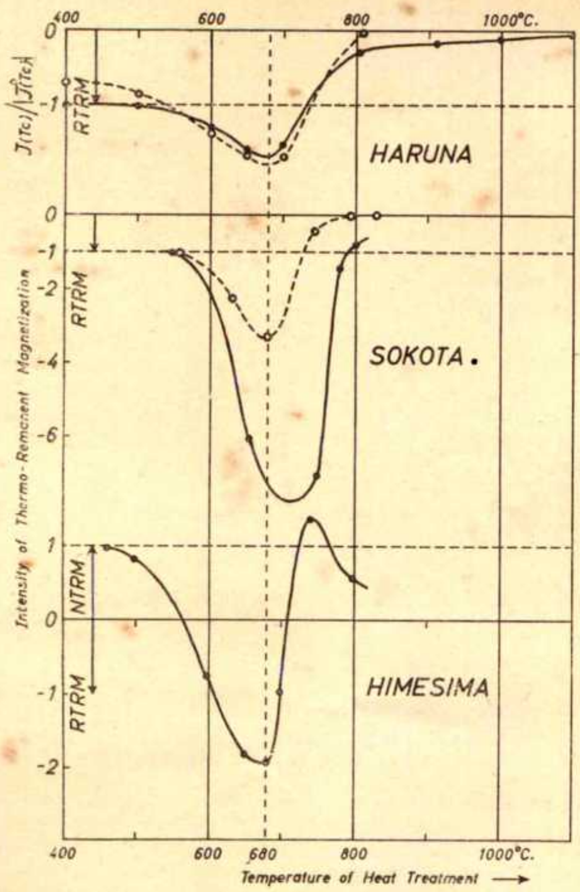

Fig. 1. Total thermo-remanent magnetization, $J(T_c)$, of ferromagnetic minerals after heat treatments at various temperatures in units of the intensity of total thermo-remanent magnetization of their original state, $J^0(T_c)$

magnetically unstable in the atmosphere at temperatures higher than about 850° C.

The same heat treatment procedure was applied on the ferromagnetic minerals separated out from Himesima rocks, which also are mainly composed of ilmenite–hæmatite solutions, their Curie points ranging from 230° C. to 250° C., but which show only the normal thermo-remanent magnetization in their original state. The result of heat treatments of this sample is illustrated in the lower diagram in Fig. 1. This shows clearly that the heat treatments at temperatures of 600°–700° C. result in the definite characteristic of the reverse thermo-remanent magnetism, the effect being a maximum again at about 680° C.

The composition of these samples was determined by chemical, magnetic and X-ray analyses, and the electron-microscope examination of fine structures of these samples before and after the heat treatment is now proceeding. Preliminary results suggest that the heat treatment at about 680° C. of these samples results in growth of the lamellar structure of intergrowth of two constituents, so that their mutual interaction becomes sufficiently strong to produce reverse thermo-remanent magnetism. Actually, an electron-photomicrograph of the original Himesima minerals showed the presence of the lamellar structures[2], but their characteristic thermo-remanent magnetism is just the same as that of Towada rock[3], namely, positive superposition of thermo-remanent magnetizations of the two constituents, suggesting that the magnetic coupling between the two constituents is very poor. After the heat treatment at about 680° C., the magnetic interaction seems to become much stronger, owing to development of the lamellar structure. This proves the possibility of changing the property of normal thermo-remanent magnetism of rock minerals to that of the reverse thermo-remanent magnetism by the artificial heat treatment. The opposite process, namely, from reverse to normal thermo-remanent magnetism, might also be possible with suitable conditions.

We believe that this kind of work on rock magnetism should be extended to many other rock samples, especially in relation to the interpretation of magnetic orientation of rocks for the purpose of palæomagnetism.

Correlation Patterns in the Chromospheric Granulation

UBEROI[1] has recently discussed a simple method of measuring the spatial correlation of the brightness fluctuations between neighbouring regions in the solar photosphere. He pointed out that, if two identical enlargements of a photograph of the solar photosphere are superimposed and one rotated from the matched position, the product of the outer radius of the circular pattern then visible and the angle of rotation gives a measure of the distance, beyond which the correlation becomes insignificant.

We have applied this technique to study chromospheric granulation using photographs taken in $H\alpha$ with a Lyot monochromator of band-width 0·7 A. Fig. 1 shows the circular correlation pattern produced

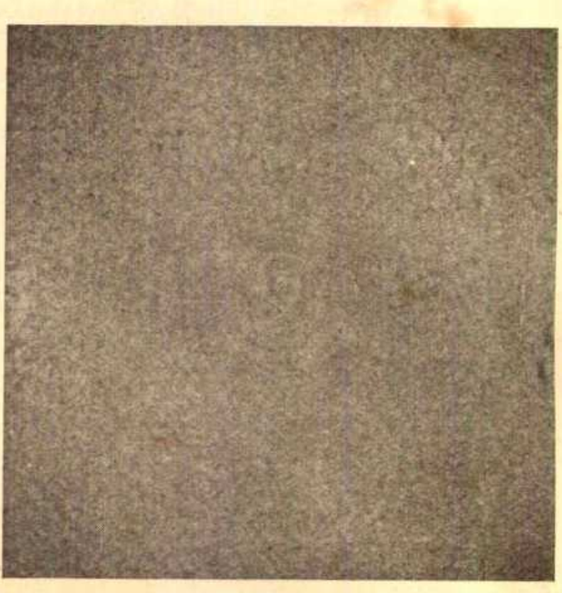

Fig. 1

from two enlargements of a chromospheric photograph taken on December 7, 1954, at 5h. 13m. U.T., this being a day of low solar activity. It is evident that the pattern shows no marked asymmetry. The correlation is found to become insignificant at distances greater than about 3 × 10^4 km., which agrees closely with the mean linear dimension of the larger elements of the chromospheric fine structure as estimated from the original photograph.

Because of the relatively long life-time of the chromospheric fine structure, it is also possible to obtain correlation patterns from photographs taken up to several hours apart. A preliminary study of the decrease in the correlation distance as the interval between the photographs is increased has led to the conclusion that the correlation is not very pronounced after a period of five to six hours.

Absorption of Ultrasound in Light Gases

Numerous workers during the past thirty years have made measurements of the absorption of ultrasound in the lighter gases (that is, oxygen and gases of lower density). The majority of the workers used interferometric techniques developed from that described by Hubbard[1]; a smaller group used optical methods[2]. An examination of absorption values obtained for the lighter gases shows that both the discrepancies between results of different workers and the range of results of individual workers are such that it is difficult to deduce any reliable data: few give any estimate of the possible errors in their results. Although Pumper[3], Krasnooshkin[4] and Bell[5] have shown that the acoustic interferometer may produce anomalous results, due to effects not previously considered, this fact has apparently not been fully appreciated. It would seem that the best published results using these techniques cannot be relied upon to better than ± 20 per cent.

Recent measurements of absorption in nitrogen and oxygen in the frequency-range 60–70 kc./s. by Parker, Adams and Stavseth[6], using a direct transmission pulse system, appear to be more reliable.

We have developed a pulse method for measuring the absorption directly at 1 Mc./s. (over a pressure-range of 0·2–2·0 atm.) which yields results to an estimated accuracy of ± 5 per cent for a single measurement. Since the major errors in the method are random, the usual statistical techniques can be used to obtain values to a higher accuracy.

Measurements in oxygen show that the absorption coefficient is 1·240 ± 0·025 times the 'classical' Stokes–Kirchoff value[7], while in nitrogen the absorption is 1·235 ± 0·015 times 'classical'. These values agree well with 1·19 ± 0·05 for oxygen and 1·22 ± 0·07 for nitrogen obtained by Parker, Adams and Stavseth[6].

All the 'error' values quoted above are the 1 per cent limits of a normal distribution.

The technique is being further developed for measurements of both absorption and velocity at frequencies up to 20 Mc./s.

Electrochemistry of Stainless Steel in Sulphuric Acid

In a study of the electrochemical behaviour of stainless steels, the electrode potential has been continuously recorded during the transformation of an air-stable oxide film to the surface state that exists in dilute, aerated sulphuric acid at temperatures between 25° and 90° C. Several definite inflexions or stages in the process have been observed which are similar in certain respects to the oscillograms obtained by Bonhoeffer and Vetter[1] in the activation and re-passivation of carbon steel in nitric acid. With stainless steel, the processes are much slower than those observed with carbon steel, so that the details of the several stages may be more readily studied. Thus, Fig. 1 shows the results obtained at 85° C. when a niobium-stabilized steel (type 347) was heated in air at 445° C. for 2 hr. and then placed in an aerated 0·1 *N* mixture of sulphuric acid and sodium sulphate which had a *p*H of 1·46. A vibrating-reed electrometer measured the potential between the steel electrode and a reference electrode kept at 24° C., so that all potentials to be given include a small potential due to the thermal gradient in the bridge. Dissolved iron was determined at intervals spectrophotometrically by use of thioglycollic acid[2].

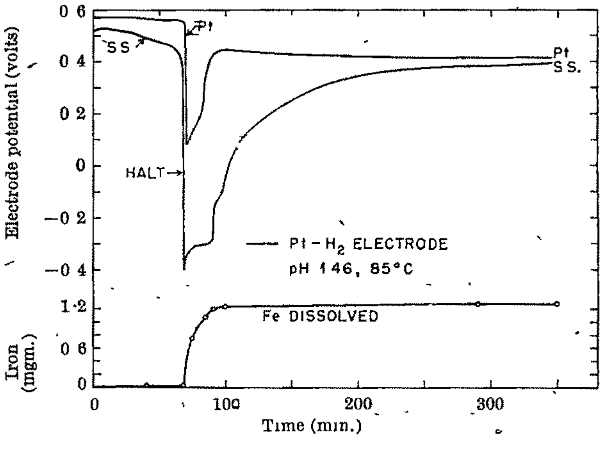

Fig. 1. Potential-time curves for stainless steel (S.S.) and smooth platinum (Pt) electrodes in aerated sulphate solution. The dissolution curve is also shown. The potential of a platinized electrode in a hydrogen atmosphere under otherwise the same conditions is indicated at − 0·3 V.

A barely detectable amount of iron dissolved during the initial passive phase. During the slow debasing, the colour became paler, and a sudden large drop in potential followed the disappearance of the last visible film, with a brief inflexion around 0 mV. versus the saturated calomel electrode (S.C.E.) as this occurred. This phase corresponds to the 'reductive-dissolution' studied by Pryor and Evans[3]; its completion left very active metal exposed and the potential fell to about − 400 mV.

From its minimum value the potential rose slightly while corrosion proceeded rapidly. What followed next was dependent upon a combination of factors which include the corrosion resistance of the specimen, the acidity, the temperature, the partial pressure of oxygen, and the geometry of the system with respect to the availability of oxygen at the interface. Fig. 1 illustrates the changes observed when using conditions that resulted in spontaneous recovery to a noble potential. Characteristically, the abrupt ennobling always began close to − 295 mV.; this point we have designated the 'critical recovery potential' for the conditions specified. The ennobling was interrupted by a brief inflexion in the region of − 140 to 0 mV., beyond which the potential rose slowly until it approached the potential indicated by a smooth platinum wire in the same solution. The ennobling process was found to be accelerated by iron (III) and copper (II) ions, among others, and experiments with radioactive iron and copper showed that both went into the film that formed during this stage of the process.

Certain specimens did not become ennobled spontaneously under the conditions indicated. In such cases, it was possible to induce the ennobling process artificially by (*a*) increasing the partial pressure of oxygen, (*b*) lowering the temperature, (*c*) raising *p*H, (*d*) adding a very small amount of an oxidizing agent such as ferric ions, cupric ions or hydrogen peroxide, or (*e*) applying briefly a small positive polarizing potential. In all such cases, if the stimulus was adequate but sufficiently small, the critical recovery potential was observed as before. Whenever, and for whatever cause, the sample passed the critical recovery potential, corrosion dropped suddenly to a very low value, as shown by the iron dissolution curve in Fig. 1.

The empirical hydrogen potential was determined for the conditions represented in Fig. 1, and at a total pressure (water vapour plus hydrogen) of 740 mm. The value obtained was − 300 mV. In the hydrogen atmosphere the stainless steel corroded rapidly at − 400 mV. and the corrosion-rate increased when the electrode was connected to the platinized electrode.

So long as the corrosion-rate is sufficiently high, oxygen is unable to depolarize the hydrogen completely and oxidize the interface. If dE/dt is positive, however, the potential will ultimately reach the critical recovery potential (approximately the hydrogen potential), hydrogen in and on the metal now becomes anodic, and by reaction with oxygen doubtless goes into transient peroxy compounds, with the sudden rise of potential observed. The subsequent brief inflexion probably represents a balance between the thermal decomposition of the peroxide and its formation from the hydrogen diffusing from the interior of the metal.

The experiments give a clear meaning to the measurements of Edeleanu[4], who found that an 18–8 stainless steel had a maximum corrosion-rate in 20 per cent sulphuric acid at 25° C. when held at a potential of about − 250 mV. Upon duplicating his experimental conditions, the 'empirical' hydrogen potential was found to be − 217 mV. Clearly, the maximum corrosion-rate should occur when the depolarization by oxygen or by an applied potential is as nearly complete as it can be without raising the electrode to the hydrogen potential. If it goes higher, hydrogen ions cease to be reduced, thereby permitting the spontaneous ennobling by reduction of oxygen.

Fuller details of this work, which was done for the U.S. Atomic Energy Commission, will be published elsewhere.

Purification of a Metal by Zone-refining one of its Salts

The technique of zone refining has been applied very successfully to the purification of metals and elements[1], especially in the semi-conductor field where very high purity is essential. With some elements, however, it happens that certain impurities have segregation coefficients (ratio of solid to liquid solubility) of the order of unity, and consequently are not swept efficiently by the molten zone.

In general, it may be possible to overcome this difficulty by carrying out the zone-refining process not on the element itself but on some suitably chosen salt (or compound) in which better segregation may be obtained. It would be necessary to choose a salt which crystallizes readily and has a convenient melting point. It must also be such that the metal can be recovered readily and without risk of recontamination.

This technique has been successfully applied to the purification of gallium. Zone-refining of the metal was not effective, as will be seen by comparing the first two columns of Table 1. The experiment was then tried of zone-refining the trichloride, which is a clear crystalline solid with a melting point of 75° C. The trichloride was formed by direct reaction of the gallium with commercial chlorine. Twenty passes of a liquid zone through an ingot of this material gave visible purification, the front end becoming transparent and practically single-crystal, whereas the rear end became highly discoloured and poly-

Table 1. Spectrographic Analysis of Impurities found in Gallium

Impurity	Gallium as purchased (parts in 10^6)	After zone-refining gallium metal: 40 zone passes (parts in 10^6)	After zone-refining gallium trichloride: 20 zone passes (parts in 10^6)
Cu	20	20	No trace (Limit 1 in 10^6)
Fe	70	60	
Ca	20	10	
Mg	20	20	
Si	70	70	
Al	10	5	
Ag	10	5	

crystalline. The clear end was cut off and dissolved in demineralized water and the metal then recovered by electrodeposition. More than 80 per cent of the metal could be recovered in this way. Spectrographic analysis of this material showed no trace of impurities, the approximate limit of detection, as determined by control experiments, being 1 in 10^6. That the electrodeposition by itself was not effective in the purification had been shown by earlier experiments.

The spectrographic work was carried out by N. Rain, of this Laboratory. Acknowledgment is made to the Admiralty for permission to publish this communication.

The Lupulone and *iso*Humulone Complex

At about the same time that we announced the existence of prehumulone[1], the presence of a fourth lupulone in hops was suggested by Howard, Pollock and Tatchell[2]. The present communication gives chromatographic proof of the existence of such a substance, which we propose to call 'prelupulone'. This chromatographic separation of the lupulone fraction of hops into its four components has been achieved by the technique described by us for the chromatography of the 'humulone complex'[1]. This is shown in the elution pattern of Fig. 1, which was obtained on a silica gel column, 1·3 cm. × 123 cm., buffered at *p*H 10·55 and containing 25 per cent methanol. The four bands were named in accordance with present knowledge of humulone chemistry[1,3].

When the 'lupulone complex' is recrystallized, the percentage of colupulone in the crystals thus obtained (still a mixture of several lupulones) is higher than in the starting material. This is probably due to the lower solubility of colupulone. It is therefore possible by repeated crystallizations (about five times from light petroleum and five times from methanol–water) to obtain pure colupulone with a melting point of 94°–96° [2]. Chromatography of this product on the column mentioned above yields a single band, corresponding exactly with the colupulone band of Fig. 1.

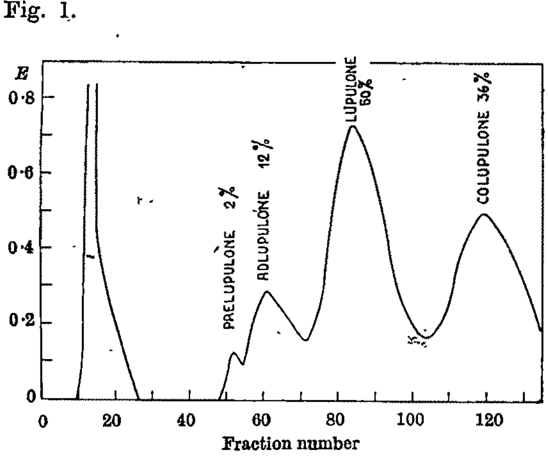

Fig. 1. Chromatography of the 'lupulone complex'. Volume of each fraction 4·5 ml. $E(1\%, 1\text{ cm.})$ lupulone in *iso*-octane = 159 ($\lambda = 275\ m\mu$)

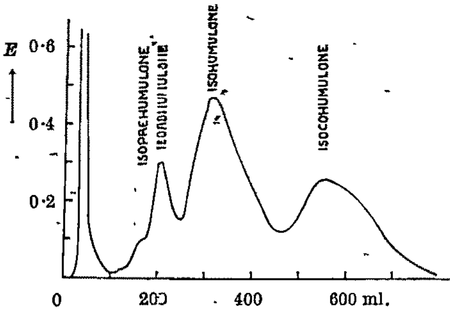

Fig. 2. Chromatography of the '*iso*humulone complex'. Volume of each fraction 6 ml. $E(1\%, 1\text{ cm})$ *iso*humulone in *iso*-octane = 276 ($\lambda = 275\ m\mu$)

The presence of an *iso*prehumulone in a beer extract can also be shown by chromatography. This separation is not as successful as for the humulone and lupulone complex, owing to extensive overlapping of the bands. An example of such a separation on a silica gel column 1·3 cm. × 85 cm., buffered at *p*H 5·22 and containing 25 per cent methanol, is shown in Fig. 2.

The beer *iso*humulone mixture for chromatographic analysis is obtained by extracting acidified (*N* sulphuric acid) beer with 2·5 times its volume of *iso*-octane. When this volume ratio is used, practically no emulsion is formed and centrifuging can be avoided. The *iso*-octane is evaporated under reduced pressure before chromatography.

Adsorption of Trace Amounts of Cations on Anion Exchange Resins by the Formation of Insoluble Salts

It has been shown[1] that cations may be precipitated around the beads of an anion exchange resin in a column, when passed in aqueous solution through the resin, which is in a form providing a suitable anion. For example, when a cobalt solution is used with a resin in the sulphide form, cobalt sulphide is formed around the beads of resin. The nature of these precipitates suggested that fairly high concentrations of precipitating anion were present in the region of the surface of the resin particles.

It seemed likely that the anion concentration within a bead of resin might be extremely high and that a very small amount of a cation in aqueous solution, diffusing into the resin, might be precipitated in the resin itself. This hypothesis was tested by passing carrier-free radioactive isotopes down columns of anion resin in suitable forms. The behaviour of these tracers was related to the solubility of the compounds concerned and to the formation of soluble complex ions.

A column, 40 cm. long and 0·3 cm. in diameter, was packed with 'Amberlite *IRA* 400' anion resin (60–85 B.S. mesh-size). The amount of resin used was calculated to have a five-fold excess of capacity over the total amount of anion to be added with the tracer. The resin was converted to the desired form by passing large volumes of solutions of acids or alkalis through the column and then washing away the excess of reagent with water. A small volume of solution containing the tracer cation (carrier-free) was run through the column, followed by several column volumes of water. The fate of the cation was found by radioactive assay of the eluate and by the detection of radioactivity on the column. The isotopes used were cæsium-137, strontium-89 (together with a small proportion of strontium-90), zirconium–niobium-95 and cerium-praseodymium-144.

In some preliminary experiments, a column in the hydroxide form allowed strontium and cæsium to run through but collected quantitatively the zirconium–niobium mixture; an oxalate column retained most of the strontium and no cæsium; and a carbonate column collected strontium. Some systematic experiments were then carried out to relate behaviour with solubility and gave the following results:

Cation	Resin form	Solubility (gm./l.)	Behaviour of cation
Cs^+	NO_3^-	190	Unabsorbed
Cs^+	ClO_4^-	20	Unabsorbed
Sr^{++}	OH^-	17·4	Unabsorbed in most experiments
Sr^{++}	$CrO_4^{=}$	1·5	About 20 per cent unabsorbed, the rest strongly absorbed
Ce^{+++}	$C_2O_4^{=}$	0·53	Absorbed
Sr^{++}	$C_2O_4^{=}$	0·05	Most of the cation absorbed

These results suggest that compounds with solubilities of 1·5 gm./l. or less can be used for the collection of their respective cations in this way. In all cases the cations were readily washed off the resin by dilute acid.

The strontium results were particularly interesting. As hydroxide, the strontium was held on the resin in a few experiments but not in most of them. This was believed to be due to the solubility of strontium hydroxide being very near the limit for collection, so that the behaviour depended on temperature, rate of elution and possibly the presence of other ions in solution. With chromate and oxalate columns the strontium was split into two forms, one of which was quickly eluted, and the other which was retained firmly on the resin. This is believed to be due to the relatively high concentration of nitrate ions in the tracer solution (the strontium-89 was used in nitric acid solution); these ions liberated appreciable amounts of chromate and oxalate ions from the resin, which in turn gave rise to small amounts of soluble association complexes with the otherwise insoluble strontium compounds. This was confirmed when the strontium tracer was stirred with a small quantity of anion resin in the hydroxide form to reduce the total anion concentration before passing down the oxalate column, when all the strontium was retained by the resin.

Since the strontium concentration was about 1×10^7 disintegrations/min./ml., the effective concentration of, for example, chromate ions in the resin necessary to 'precipitate' the strontium would be about 1×10^4 *M*. It is more likely, therefore, that the high concentration of chromate ions in the resin promotes the formation of a radio-colloid, which is then adsorbed on the resin.

This method of collecting cations in trace concentrations has the advantages of being more efficient and more selective than the conventional co-precipitation technique. It is now being used for rapid separations of individual fission products from mixtures, and may also be used for forecasting the insoluble compounds of elements of which only trace amounts are available.

We thank E. F. Kemp for a helpful discussion, and the Managing Director, U.K. Atomic Energy Authority (Industrial Group), for permission to publish this communication.

Effect of Copper Cyanide upon the Formation *in vitro* of Melanin

As already reported, copper–xanthopterin accelerates the autoxidation of 3,4-dihydroxyphenylalanine[1]. In the course of further work, we have observed some interesting effects with cupric ions.

When potassium cyanide was added, in order to capture copper, to the solution containing the copper–xanthopterin and dihydroxyphenylalanine, the oxygen uptake was much enhanced and rapid formation of melanin was brought about. Such a result was not expected at first, for it is generally known that copper oxidases are inhibited by cyanides. We then found that the copper cyanide acted catalytically upon the autoxidation of dihydroxyphenylalanine, showing a rate of oxygen uptake as high as 70 µl. per hr., in contrast with 48 µl. consumed by the system containing copper–xanthopterin and dihydroxyphenylalanine.

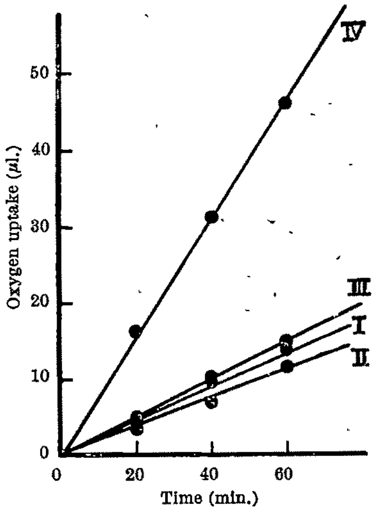

Fig. 1. Manometric determination of the accelerating effect of copper cyanide upon the autoxidation of pyrocatechol (*p*H 7·8, 37·5° C.)
Curve IV: 1·0 ml. of *M*/15 phosphate buffer, 1·0 ml. of 5×10^{-4} *M* potassium cyanide, 0·5 ml. of 5×10^{-4} *M* cupric sulphate, 0·3 ml. of distilled water and 0·5 ml. of 10^{-3} *N* sodium hydroxide in the main chamber of the flask. Curve III: 1·0 ml. of 5×10^{-4} *M* potassium cyanide in (IV) replaced by 1·0 ml. of distilled water. Curve II: 0·5 ml. of 5×10^{-4} *M* cupric sulphate in (IV) replaced by 0·5 ml. of distilled water. Curve I: 1·0 ml. of 5×10^{-4} *M* potassium cyanide and 0·5 ml. of 5×10^{-4} *M* cupric sulphate in (IV) replaced by 1·5 ml. of distilled water. Other components in the main chambers are all common to (IV).
Each of the side arms of the flasks contained 0·5 ml. of 10^{-2} *M* pyrocatechol in 10^{-3} *N* hydrochloric acid, and each of their wells, 0·2 ml. of 10 per cent potassium hydroxide. The gas space of the manometric flask was filled with air. The pyrocatechol solution was tipped from the side arm into the main chamber when the flask reached thermal equilibrium

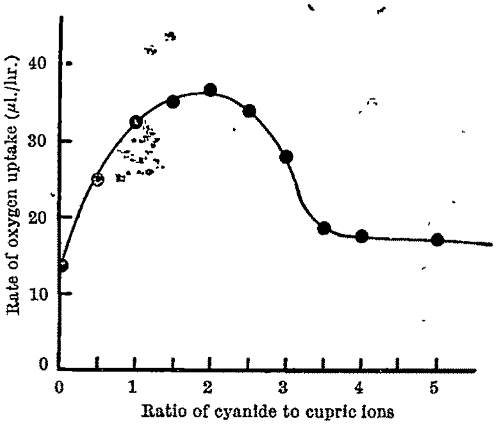

Fig. 2. Manometric determination of the effect of the mixing ratio of potassium cyanide to cupric sulphate upon the catalysis of the autoxidation of pyrocatechol (*p*H 7·8, 37 5° C.).
Each of the experimental flasks contained 0·2 ml. of 5×10^{-4} *M* cupric sulphate, 0·1 ml. of potassium cyanide of various concentrations ($0{\cdot}5 \times 10^{-3}$ *M*, 1×10^{-3} *M*, $1{\cdot}5 \times 10^{-3}$ *M*, 2×10^{-3} *M*, . . . , 5×10^{-3} *M*), 1 0 ml. of *M*/15 phosphate buffer, 0·5 ml. of 10^{-2} *N* sodium hydroxide, and 1 0 ml. of distilled water in the main chamber. In the control flask, 0·1 ml. of potassium cyanide was replaced by 0·1 ml. of distilled water, all the other components being the same as those in the experimental flasks. Each of the side arms of the flasks contained 0 5 ml of 10^{-2} *M* pyrocatechol dissolved in 10^{-2} *N* hydrochloric acid, and each of the wells, 0 2 ml. of 10 per cent potassium hydroxide. Other conditions were the same as those in the experiment shown in Fig. 1. The oxygen uptake per hour in the experimental, as well as control, flasks was plotted against the concentration ratio of potassium cyanide to cupric sulphate

In an earlier paper[2], it was shown that the accompanying xanthopterin checked the accelerating effect of cupric ions upon the autoxidation of pyrocatechol. There was, however, a remarkable production of the black pigment. Now copper cyanide, though it accelerates considerably the rate of autoxidation of pyrocatechol as well as dihydroxyphenylalanine, is not very superior to cupric ions alone as regards catalytic activity on pigment formation from pyrocatechol. In these ways at least, copper cyanide seems to differ considerably from copper–xanthopterin, probably in its mode of action toward the autoxidation processes.

As seen in Fig. 1, the cupric ion slightly accelerates, whereas the cyanide inhibits, the autoxidation of pyrocatechol. Nevertheless, the addition of both cupric ions and cyanide resulted in a definite acceleration of autoxidation. We then examined the effect of altering the ratio of copper to cyanide and found, as shown in Fig. 2, that the ratio 1 : 2 gave the maximum acceleration. It was also found that the addition of ethylenediamine, xanthopterin and certain other chelating agents to the copper cyanide–pyrocatechol system decreases the rate of oxidation.

From these results it was thought that certain complexes of copper and cyanide were produced and they acted more or less catalytically. This was also suggested by the stepwise change of the colour of the cupric sulphate solution with the increasing addition of potassium cyanide: from pale blue, through green, greenish-brown, and orange-red, to dark red. The cupric cyanide complex is known to be unstable[3].

The solution of copper and cyanide becomes more and more alkaline with the increase of the latter, but maximum activity in accelerating oxygen uptake, as mentioned above, occurs with a mixing ratio of 1 : 2. This suggests that the active species contains co-ordinated with it not more than two cyanide ions. As regards copper–xanthopterin, the optimal mixing ratio is 1 : 1 (unpublished work). From the optimal mixing ratios of these complexes, their substrate may be the bidentate donor derived from pyrocatechol and its derivatives[4].

Other substances such as thiocyanate and ammonia, when added to the cupric sulphate solution, affected the autoxidation of dihydroxyphenylalanine similarly to cyanide, although their activities were much lower. The order of the activity was $CN \gg CNS \gg NH_3$. Bivalent metallic ions other than cupric were investigated also; but if mixed with cyanide or thiocyanate or ammonia, they did not accelerate the autoxidation of either pyrocatechol or dihydroxyphenylalanine.

Quantitative Determination of Acetylcholinesterase Activity in Individual Nerve Cells

MOST of our knowledge concerning the topical distribution of cholinesterases in the mammalian nervous system is derived from studies on tissue sections by various histochemical methods. In order to obtain more detailed information about the localization of this enzyme in the neurone, a modified thiocholine method[1] has now been applied to single cells dissected out from living tissues[2]. Quantitative data regarding the cholinesterase contents in individual nerve cells are, however, still lacking.

In 1937, Linderstrøm-Lang introduced a microgasometric method based on the principle of the Cartesian diver[3]. Later, the diver technique was applied to studies on cholinesterase and proved useful in analysing small samples of blood[4], embryonic tissue extracts and tissue sections[5]. Recently, a micro-diver technique has been developed for cholinesterase measurements in single megakaryocytes of the bone-marrow of the rat (Zajicek and Zeuthen, unpublished work), and the method was refined further for studying the increase of the specific cholinesterase or acetylcholinesterase activity during the maturation process of megakaryocytic cells (Zajicek, unpublished work). The present communication reports the application of the micro-diver technique for the determination of the acetylcholinesterase contents in a single nerve cell.

Albino rats, weighing about 200 gm., were killed by decapitation without anæsthesia. The spinal, sympathetic and parasympathetic ganglions were isolated and placed in substrate-bicarbonate Ringer's solution. Individual nerve cell bodies and a part of their neurites 100–200μ long were dissected out by micromanipulation. The divers were charged and a 7×10^{-3} *M* solution of acetylthiocholine was used as substrate (Zajicek and Zeuthen, unpublished work). The esterase activity was expressed as the amount of carbon dioxide evolved from the bicarbonate buffer by the acid formed during the enzymatic hydrolysis of acetylthiocholine. The sensitivity of the divers employed was of the order of 2×10^{-6} µl. carbon dioxide.

The esterase activity curves for a cell body, isolated from a sympathetic ganglion (filled circles) and that of its neurite (open circles) are given in Fig. 1. This graph shows that the cell body liberated about 620×10^{-6} µl. carbon dioxide, and a part of its neurite 130µ long 235×10^{-6} µl. carbon dioxide per hour, corresponding to the hydrolysis of about $7{\cdot}6 \times 10^{-3}$ µgm. and $2{\cdot}9 \times 10^{-3}$ µgm. of acetylthiocholine respectively.

Recent findings on the different types of cholinesterases indicate that acetylcholinesterase is the physiologically important enzyme in splitting acetylcholine in the animal system[6]. When measuring the enzymic activity in a single cell, the differentiation between cholinesterase and acetylcholinesterase cannot be achieved by current substrate specificity or activity-substrate concentration relationship tests for reasons discussed in detail elsewhere.

It has recently been found that 8×10^{-7} *M* mipafox (*bis*-mono*iso*propylamino-fluorophosphine oxide) completely inhibits the non-specific serum cholinesterase, whereas it affects acetylcholinesterase activity only in concentrations higher than 6×10^{-6} *M* [7].

The quantitative determination of non-specific cholinesterase and acetylcholinesterase activity in a single cell with the aid of the inhibitor involves three main steps: (i) the determination of the whole acetylthiocholine-splitting capacity of the cell; (ii) the introduction of a 6×10^{-6} *M* solution of mipafox which inhibits the non-specific cholinesterase into the diver; (iii) the subsequent measurement of the acetylcholinesterase activity (Zajicek, unpublished work).

The esterase activity curves of a cell body isolated from a spinal ganglion (crosses) and of a 100-µ long part of its neurite (filled circles), and, finally, of a sample of purified serum cholinesterase, before and after treatment with mipafox (open circles), are shown in Fig. 2. The graph shows that the cell body and its neurite, which hydrolysed 17×10^{-3} and $1{\cdot}5 \times 10^{-3}$ µgm. of acetylthiocholine per hr., respectively, exhibited the same esterase activity after treatment with mipafox as before treatment, whereas the non-specific cholinesterase was completely inactivated by the inhibitor. It is therefore concluded that the esterase estimated in the single spinal ganglion cell was an acetylcholinesterase ('specific' or 'true' cholinesterase), that is, the enzyme which is claimed to be connected with the mechanism of the transmission of nerve impulse[6].

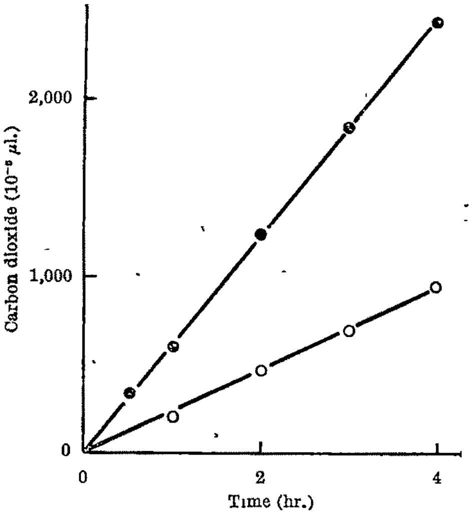

Fig 1. Esterase activity curves of a cell body (37µ) isolated from a sympathetic ganglion of rat (filled circles) and that of a 130-µ long part of its neurite (open circles)

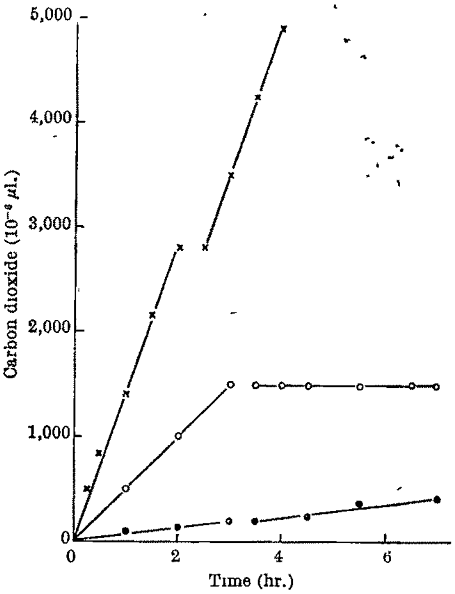

Fig. 2. Esterase activity curves of a cell body (44µ) isolated from a spinal ganglion of rat (crosses), of a 100-µ long part of its neurite (filled circles) and of a sample of purified serum cholinesterase (open circles), before and after treatment with mipafox

A detailed report of the inter- and intra-cellular distribution of acetylcholinesterase in ganglion cells will be published later.

An Unidentified Amino-sugar present in Cell Walls and Spores of Various Bacteria

A substance reacting as a hexosamine but which is not glucosamine or galactosamine has been found in 6 *N* hydrochloric acid hydrolysates of a variety of bacterial cell walls by Cummins and Harris[1] and in peptides isolated from spores of *Bacillus megatherium*, *B. subtilis* and *B. cereus* by Strange and Powell[2]. There is evidence that in all cases the same substance is involved, and recently in this laboratory a similar compound was isolated from acid hydrolysates of cells of *Micrococcus lysodeikticus* in sufficient quantity

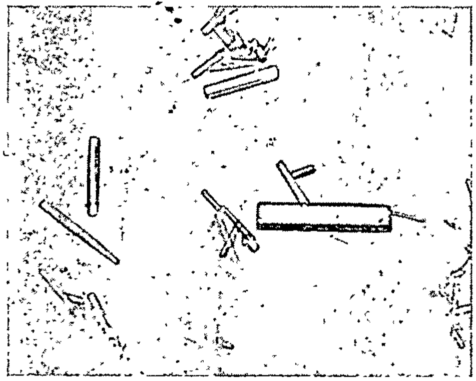

Fig. 1. An unidentified amino-sugar from *B. megatherium* spore peptide, crystallized from ethanol–water. × 100

for comparison with that from spore peptide, which showed that it was identical in a number of properties. The amino-sugar would therefore seem to be widely distributed in bacteria. The base has now been obtained in crystalline form from acid hydrolysates of spore peptide (Fig. 1) by the use of ion-exchange resins. Investigation of the crystalline compound has shown that it is not a simple hexosamine; for example, after treatment with ninhydrin according to the method of Stoffyn and Jeanloz[3], followed by paper chromatography, a spot was obtained which reacted with aniline phthalate[4] and other sugar spray reagents like a pentose but which had an R_F value considerably lower than that of arabinose, lyxose, xylose or ribose. This product reduced ammoniacal silver nitrate but did not react with naphthoresorcinol–trichloracetic acid[5].

So far, the amino-sugar has always been found in the presence of glucosamine or glucosamine and galactosamine[1,2], and since it reacts like them in three methods for their estimation, namely, those of Elson and Morgan[6], Dische and Borenfreund[7] and Tracey[8], it will be estimated with them as hexosamine. It was thought desirable to determine the quantitative effect of the substance in these three methods. The crystals were dried over phosphorus pentoxide *in vacuo* at 60°.

Using the Immers and Vasseur[9] modification of the Elson and Morgan method, the colour obtained had an absorption maximum near 520 mμ, compared with that of 530 mμ for the glucosamine or galactosamine derivatives[2]. The relationship between light absorption at 520 and 530 mμ and concentration, for the substance and glucosamine (base), is shown in Fig. 2. When the light absorption of both derivatives was measured at 530, 520 and 510 mμ, the colour produced by the amino-sugar was equivalent to 56, 69 and 77 per cent, respectively, of that produced by an equal weight of glucosamine.

Using the Dische and Borenfreund method, the light absorption of the colour produced measured at 492 mμ minus that measured at 520 mμ was 53 per cent of that produced by an equal weight of glucosamine (base).

Using the Tracey alkaline distillation method, the ammonia liberated from the substance was equivalent to 5 per cent nitrogen compared with 7·8 per cent for glucosamine (base).

From these results it is evident that the substance cannot be estimated as a hexosamine with reference to glucosamine unless the conversion factor is known for each method. A simple method of detecting it is to take readings of the absorption of the Elson and Morgan colour at 510 and 530 mμ. The ratio $\frac{-\log T\ 530\ m\mu}{-\log T\ 510\ m\mu}$ is greater than 1·1 for the glucosamine and galactosamine derivatives and less than 0·9 for the amino-sugar derivative. It is also possible, by means of this ratio, to detect it in solutions containing these hexosamines, providing its concentration with respect to them is high enough.

For the estimation of the substance in the presence of glucosamine or galactosamine, advantage may be taken of the fact that the ion-exchange resin I*R*–120 (H) (obtainable from B.D.H., Ltd.), buffered to *p*H 6·05, will remove these hexosamines but not the amino-sugar from aqueous solution. A column of I*R*–120 (H) was prepared and *M* sodium dihydrogen and disodium phosphate buffer, *p*H 6·05, passed through until the eluent was at this *p*H. The resin was washed with de-ionized water until the eluent was free from phosphate and dried at room temperature on filter paper. The solution for analysis was adjusted to *p*H 6·0; in the case of acid hydrolysates, this was achieved by the use of I*R*–4*B* (OH). The solution was diluted, if necessary, to contain not more than 100 μgm./ml. hexosamine-reacting material (as glucosamine). A sample (5 ml.) was treated with buffered resin (approximately 1 gm.) in a stoppered tube on a rotary shaker for 30 min. The solution was filtered free from resin through a Whatman No. 1 filter paper (5·5 cm.) and the Elson and Morgan reaction carried out with an aliquot of the filtrate (1–2 ml.). In the absence of the pure substance, a glucosamine standard may be used and the result multiplied by a factor, namely, 1·78, 1·45 or 1·3 for measurements taken at 530, 520 or 510 mμ, respectively, to give the approximate concentration. Recoveries with solutions containing the substance and glucosamine or galactosamine were 98–101 per cent when compared with a standard of the pure amino-sugar. Acid hydrolysates of cell walls of vegetative *B. megatherium*, *B. subtilis* and *B. cereus*

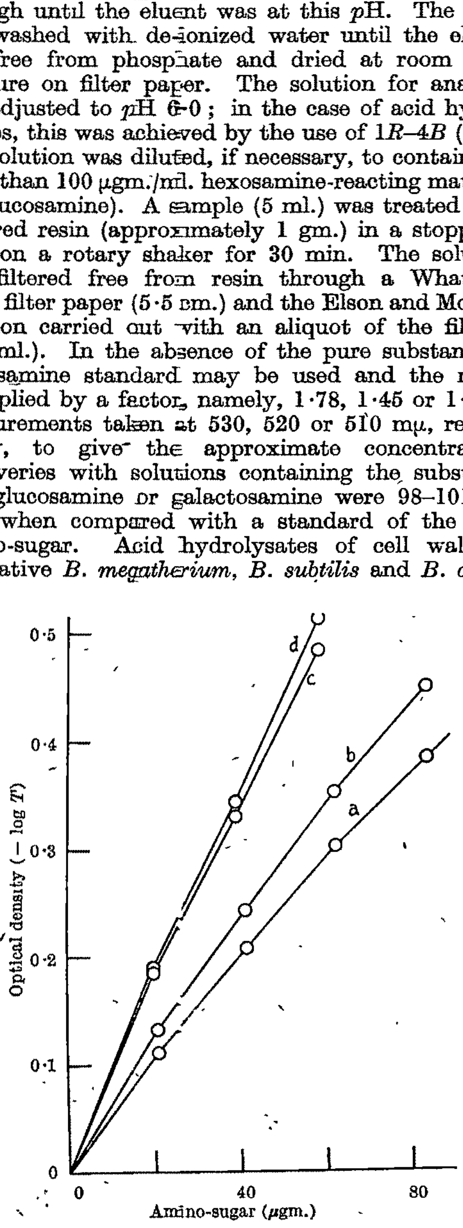

Fig. 2. Concentration/—log *T* relationships for the amino-sugar and glucosamine derivatives in the Elson and Morgan reaction: (*a*) amino-sugar at 530 mμ; (*b*) amino-sugar at 520 mμ; (*c*) glucosamine at 520 mμ; (*d*) glucosamine at 530 mμ

were found to contain 10, 11·6 and 4·3 per cent, respectively, of the amino-sugar.

Work on the identification of the substance is proceeding in this laboratory.

Vitamin B_{12} Activity of *Chlorella vulgaris* Beij and *Anabaena cylindrica* Lemm

Microbiological tests by means of vitamin B_{12}-dependent bacteria and *Euglena gracilis* have shown that higher plants contain only traces (less than 1 µgm. per 100 gm. dry weight) of vitamin B_{12}, whereas microbiological activity corresponding to 10–50 µgm. vitamin B_{12} per 100 gm. dry weight has been reported in a number of algae.

Several substances, such as factor *A* and pseudo-vitamin B_{12}, are closely related chemically to cobalamin and capable of supporting growth of the bacteria and *Euglena* used for microbiological assay of the vitamin[1,2]; but they cannot replace cobalamin in the nutrition of higher animals[3]. Some micro-organisms are known to synthesize these substances as well as vitamin B_{12} itself[2,4]. The vitamin B_{12} activity of two algae was therefore investigated to determine whether this was due to cobalamin or to one or more of the related factors. Pure cultures of algae, which had been maintained free from bacteria during many transfers on inorganic media, were employed to ensure that any vitamin B_{12} activity detected must have originated from the synthetic activity of the organisms studied.

Vitamin B_{12} assays were carried out by a modification of the *E. coli* mutant plate-assay method[5], the solution for assay being obtained by extracting the algae with hot aqueous methanol in the presence of ammonia and cyanide. The nature of the substances present was determined by chromatography, ionophoresis and bio-autography[6]. By these tests the sample of *Chlorella vulgaris* was shown to contain 6·3 µgm. cobalamin per 100 gm. dry weight; no other compounds showing vitamin B_{12} activity could be detected. The results obtained with *Anabaena cylindrica* are shown in Table 1.

About 65–70 per cent of the activity of the *Anabaena* was due to vitamin B_{12}, the remaining effects being caused by the presence of pseudo-vitamin B_{12} and traces of factors *A* and *B*. In one experiment, cobalt (5 p.p.m.) was added to the medium to determine whether additional cobalt would allow synthesis of more vitamin B_{12}. Although the concentration of vitamin B_{12} was thereby almost doubled, scarcely any more total vitamin B_{12} activity was detected, because the dry-weight yield of alga was simultaneously depressed.

Table 1

Added cobalt	Total vit. B_{12} activity (*E coli*) per gm. dry wt.	Activity of B_{12} and related substances (in terms of B_{12}) per gm. dry weight			
		Vit B_{12}	Pseudo-vit. B_{12}	Factor *A*	Factor *B*
Nil	0·63 µgm.	0·44 µgm.	0·19 µgm.	trace	trace
5 p p m.	1·1 µgm.	0·70 µgm.	0·40 µgm	trace	trace

The cobalamin content of *Chlorella* used in these studies is of the same order as the microbiological activity reported by Combs[7] for this organism: it indicates that the algae, grown under controlled conditions, may synthesize sufficient cobalamin to contribute to the dietary needs (up to about 5 µgm./100 gm. food) of higher animals and man.

The higher animals and many Protista, for which vitamin B_{12} is an essential nutrient, have been thought to be dependent on bacterial and fungal synthesis of the vitamin. The presence of cobalamin in at least two different algae may point to an alternative source of this nutrient, particularly for B_{12}-dependent organisms living in soil or water and for the food chains of animals living on these organisms.

Influence of the Adrenal Cortex on Wool Growth and its Relation to 'Break' and 'Tenderness' of the Fleece

We were interested to know whether the adrenal cortex exerted a depressant action on wool growth in sheep. Such a mechanism might underlie the decline in wool growth observed in winter[1] and during pregnancy[2], since cold and gestation are known to increase adrenocortical activity in other species[3]. The marked increase in the number of active follicles which begins about ten days after birth in the lamb (Ferguson, K. A., Schinckel, P. G., Carter, H. B., and Clarke, W. H., in preparation) may possibly be due to release from adrenocortical inhibition. Field-observations link the occurrence of 'break' or 'tenderness' of the fleece[4] with disease, advanced pregnancy or environmental stresses which may be expected to stimulate secretion of adrenocorticotrophic hormone.

We have observed the effects on wool growth of treating sheep with adrenocorticotrophic hormone and with cortical steroids. The sheep were main-

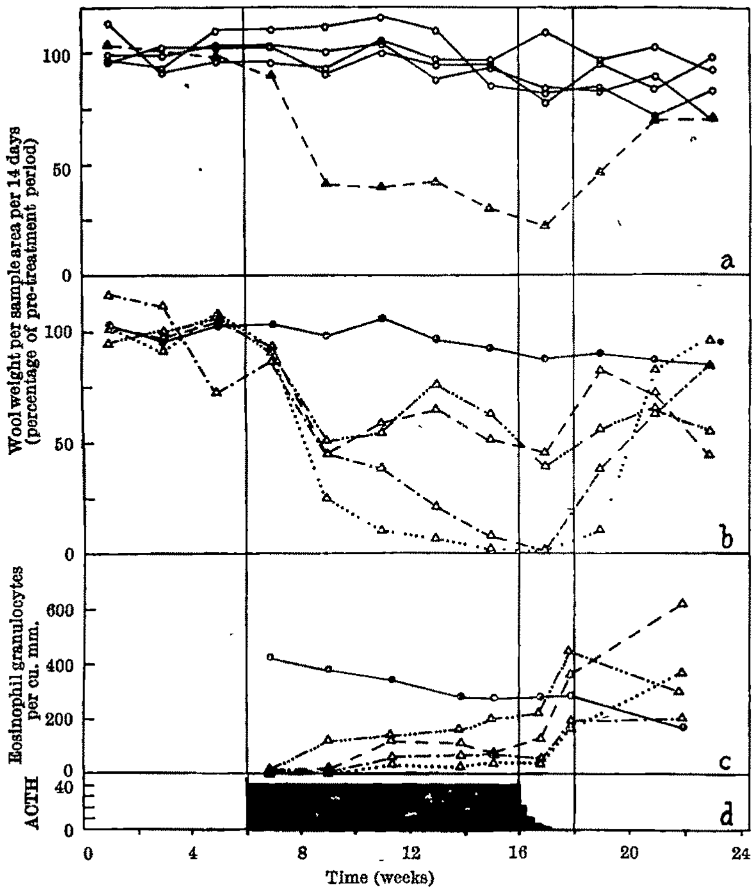

Fig. 1. Wool growth and blood eosinophil granulocyte count of sheep injected daily with adrenocorticotrophic hormone. (*a*) ○—○, untreated; ▲- - -▲, treated (mean); (*b*) and (*c*), ●—●, untreated (mean); △—···—△, *A* 91; △——△, *A* 79; △—·—△, *A* 84; △····△, *A* 89; (*d*) dose of adrenocorticotrophic hormone in I.U./sheep/24 hr.

tained in pens on a constant food intake. Wool growth was measured by the periodic clipping of a sample area defined by tattoo lines. Four ewes received daily intramuscular injections of 40 I.U. of long-acting adrenocorticotrophic hormone (Acton) for ten weeks.

The results are shown in Fig. 1. Wool growth was significantly decreased in the treated sheep ($P < 0.01$). In two sheep, wool growth diminished progressively until completely arrested, and rose sharply after cessation of treatment. In the other two animals, a degree of refractoriness developed after an initial decrease in wool growth. Fibre thickness and length growth were reduced and histological sections revealed many follicles that had shed their fibres and undergone varying degrees of involution. Primary follicles shared this effect, though to a lesser degree than secondary follicles. Coinciding with the resumption of wool growth as determined on the sample area, a 'break' appeared in the fleece above the surface of the skin in all sheep treated. Numerous shed roots and new growing tips resembling those of lambs' wool were discernible microscopically in this part of the staple, whereas other fibres, though continuous through the region of break, were reduced in diameter.

The number of circulating eosinophils was reduced by treatment with adrenocorticotrophic hormone. This reduction was less persistent in those sheep showing refractoriness to treatment, suggesting that the adrenals of these sheep were unable to respond to continued intense stimulation. No refractoriness has been noted in four sheep treated with cortisone. The serum of a sheep refractory to adrenocorticotrophic hormone failed to protect hypophysectomized rats against the effect of the hormone in restoring the weight of adrenals, indicating that antibodies to the hormone were not the cause of the refractoriness.

A response resembling that to adrenocorticotrophic hormone was produced in four ewes by the daily intramuscular injection of 1·8 mgm. cortisone acetate per kgm. body-weight for eight weeks. Again the appearance of the 'break' above the skin coincided with the resumption of wool growth four to six weeks after cessation of treatment. The local application of an ointment containing 0·1 per cent of 9-α-fluorohydrocortisone (Merck) to the sample area on three sheep suppressed wool growth and induced local skin changes resembling those produced by the systemic treatments described, while normal wool growth continued on sample areas sham-treated with the ointment base on the opposite sides of the same sheep. Treatment of other sheep with a 2·5 per cent hydrocortisone ointment (Merck) produced a much smaller response.

Experiments are in progress to determine whether the cortical secretion of the normal sheep is sufficient to limit wool growth. Comparisons are being made of the wool growth of adrenalectomized sheep maintained on different levels of cortisone and deoxycorticosterone.

The above experiments suggest that a temporary hyperactivity of the adrenal cortex may be a common physiological mechanism underlying the occurrence in the field of 'tenderness', 'break', 'rising of the fleece', and possibly the 'cotted fleece'. However, the degree of adrenocortical stimulation which occurs following natural stresses which cause 'break' remains to be determined. Further investigation is also required to test whether variations in adrenal cortical activity are of importance in determining natural variations in wool growth, such as those due to individuality, breed, nutrition, gestation and season.

Zinc in Aspermic Human Semen

Normal human seminal plasma has been shown to contain a higher concentration of zinc than any tissue except sperm[1]. The sperm contain a very high concentration of zinc, but their removal from semen by centrifugation causes no significant reduction in the zinc concentration of the fluid because of their small relative volume. No previous opportunity had occurred for analysis of naturally aspermic semen, but recently a specimen of this nature was received. It had not been collected in specially cleaned glassware, but any contamination due to this fact could not have added more than a few μgm./ml. to the zinc content.

The centrifuged deposit from the whole specimen was examined by phase microscopy and by the staining method of Isenberg[2] and found to contain a few epithelial cells, but no sperm. The volume of the semen was 5 ml.

Zinc was estimated in 1 ml. of the plasma by the method of Vallee and Gibson[3]. The dry weight was 7·6 gm./100 gm. and the zinc concentration 234 μgm./ml. This result did not differ significantly from normal: four specimens of normal human seminal plasma contained 134 ± 59 (S.D.) μgm. zinc/ml.

It is known that dietary zinc deficiency will cause a reduction of androgenic hormone production and aspermia in rats[4]. The wide distribution of zinc in Nature makes dietary zinc deficiency in man very improbable, and the normal volume and the high zinc content of this semen suggest normal prostatic function. The donor was clinically normal, with no evidence of androgenic insufficiency.

Reticulocyte Enzymes and Protein Synthesis

The hæmoglobin of red cells appears to be synthesized during the early stages of maturation, and its formation is more or less complete by the time the cells leave the bone marrow. Although reticulocytes have practically their full complement of hæmoglobin, evidence from amino-acid incorporation studies[1] suggests that these cells, unlike mature erythrocytes, still have protein-synthesizing capacity. In view of this, it was felt that it would be of interest to see if certain enzymes were at a high level of activity in reticulocytes; Table 1 summarizes the results of a preliminary investigation of the level of activity in the two types of cell for a number of enzymes which might be involved in some way in a protein-synthesizing mechanism.

In addition to the enzymes shown, attempts were made to detect glutamine synthetase and enzymes synthesizing glutathione. However, under the conditions of assay which were tried, such activities were not detected in either erythrocytes or reticulocytes.

Table 1

Enzymatic activity	*p*H	Activators	Approximate increase in activity in reticulocyte preparations
Cathepsin	3·2	none	6-fold
Cathepsin	7·5	0·001 *M* Zn^{++}	no increase
Glycylglycine dipeptidase	7·8	0·001 *M* Co^{++}	8-fold
Leucine amino-peptidase	7·8	0·001 *M* Mn^{++}	2-fold
Tripeptidase	7·1	none	2- to 3-fold
Liberation of inorganic phosphate from adenosine tri-, di- and mono-phosphate	7·5	0·001 *M* Mg^{++}	2- to 3-fold
Acid phosphatase	6·0	none	3- to 5-fold
Alkaline inorganic pyrophosphatase	7·5	0·025 *M* Mg^{++}	8-fold
Acid inorganic pyrophosphatase	5·2	none	12-fold

The phosphatases listed in Table 1 were investigated in view of the possibility that their *in vivo* function may be concerned with the transfer of phosphate bond energy utilized in the linking of amino-acids. The reticulocyte preparations were similar to those used in the amino-acid incorporation studies of Borsook[1], that is, preparations of rabbit blood containing 70–90 per cent reticulocytes, obtained following reticulocytosis induced by phenylhydrazine. The assays were carried out on whole hæmolysates obtained by freezing and thawing the washed cells, and activities were expressed per milligram of protein nitrogen.

During the transition from reticulocyte to erythrocyte, much of the cellular protein, other than hæmoglobin, disappears, and it might be expected that, relative to total protein nitrogen, a generally higher level of enzymatic activity might be found in the former type of cell. This may account for the fact that most of the enzymes studied showed some increase in activity in reticulocytes.

However, from Table 1 it is apparent that some enzymes are increased to a greater extent than the others: namely, cathepsin active at *p*H 3·2, one particular peptidase (glycylglycine dipeptidase), and inorganic pyrophosphatase.

The possibility that cathepsins have a synthetic function has long been considered, and there appears to be some correlation between the rate of growth, or of protein synthesis, and the level of catheptic activity in various tissues[2,3]. On the other hand, recent reports that cathepsins are mitochondrial enzymes[4] are not in accord with a protein-synthesizing function, as the latter process appears to be associated with microsomal particles. It has been suggested[3] that catheptic activity is concerned with the provision of free amino-acids for utilization in protein formation, rather than with the synthetic mechanism itself.

The observation of a specific increase in dipeptidase activity is of interest in relation to recent reports by Binkley[5], who, in the course of attempts to purify cysteinyl glycinase from swine kidney, obtained a soluble fraction which possessed a very high non-specific dipeptidase activity and which was apparently non-protein in nature. This material exhibited some of the properties of a polynucleotide, and in view of this, it was suggested that *in vivo* the activity might be related to protein biosynthesis.

Among the phosphatases studied, the largest increases were found in the case of the inorganic pyrophosphatases. This observation may have a bearing on results obtained by Hoagland and Keller[6], who have formulated the following scheme for the carboxyl activation of amino-acids (detected in their experiments by hydroxamate formation):

$$E + \mathrm{ATP} \rightleftharpoons E(\mathrm{AMP{-}PP})$$
$$E(\mathrm{AMP{-}PP}) + \mathrm{AA} \rightleftharpoons E(\mathrm{AMP{-}AA}) + \mathrm{PP}$$
$$E(\mathrm{AMP{-}AA}) + \mathrm{NH_2OH} \rightleftharpoons E + \mathrm{AMP} + \mathrm{AA{-}NH.OH}$$

If the activation of amino-acids prior to incorporation into protein takes place by a general mechanism such as the above, then a function for the intracellular pyrophosphatase is apparent: to split the inorganic pyrophosphate formed, thus providing free orthophosphate for utilization in the regeneration of adenosine triphosphate (presumably through a concomitant glycolytic process). The higher inorganic pyrophosphatase activity in reticulocytes could be related in this way to the protein-synthesizing capacity of these cells.

Detailed reports on the above investigations are in preparation for submission to the *Biochemical Journal*. This work is supported by a grant from the Secretary of State for Scotland on the recommendation of the Advisory Committee on Medical Research.

Polyembryony in *Cassia*

DURING an investigation into a presumed hybrid swarm among *Cassias*[1], seeds with twin embryos were found. An examination of the seeds of different species of *Cassia* that were available has shown the occurrence of polyembryony to be geographically widespread and remarkably common within several species. Table 1 gives the percentage of twins and triplets (in brackets) found in different collections of fifty to a hundred seeds.

Table 1. PERCENTAGE OF TWINS AND TRIPLETS (IN BRACKETS) IN DIFFERENT COLLECTIONS OF SEED

Australian species of *Cassia*	1	2	3	4	5
C. artemisioides Gaud.	10 (1)	25	10 (1)	23 (3)	8
C. australis var. *revoluta* Benth.	0				
C. desolata var. *involucrata* J. M. Black	16 (1)				
C. eremophila A. Cunn	40 (2)	20 (2)	5	24	
C. phyllodinea R. Br.	14 (1)				
C. sturtii R. Br.	3	21	9	40 (4)	14 (2)

The exotic species *C. bicapsularis*, *C. cana*, *C. corymbosa*, *C. fistula* and *C. leptophylla* contained no twins in single samples of fifteen to fifty seeds.

Among the twins and triplets the embryos varied from equality in size to one large and one small, and one large and two small respectively, gross inequality being the general case. Fused embryos and others with extra or reduced cotyledons were also frequent. The pairs of large twins at least were viable.

These extra embryos could arise from several sources. The occurrence of cleavage polyembryony or of several embryo sacs would not be apomictic in nature, but the first case would lead to the production of identical twins as would apomictic embryos. The latter could have developed from cells of the nucellus and integuments, or in some cases from the synergids. Twins arising from several embryo sacs would not be identical. However, many genera are facultative apomicts, and both sexual and apomictic reproduction may occur simultaneously[2]. Evidence for this in *Cassia* was indicated when one plant, presumed to be a hybrid on morphological characters, failed to segregate but produced twins and other abnormal seedlings, while a second plant produced morphologically different seedlings from each of two pairs of twins.

All the Australian species listed belong to the section *Psilorhegma*, which is well developed in Australia, but the varied biotypes of which have resulted in taxonomic confusion, particularly in the species complex centred about *C. sturtii*. The preservation of the intermediates could be the result of both apomixis and of sexual reproduction.

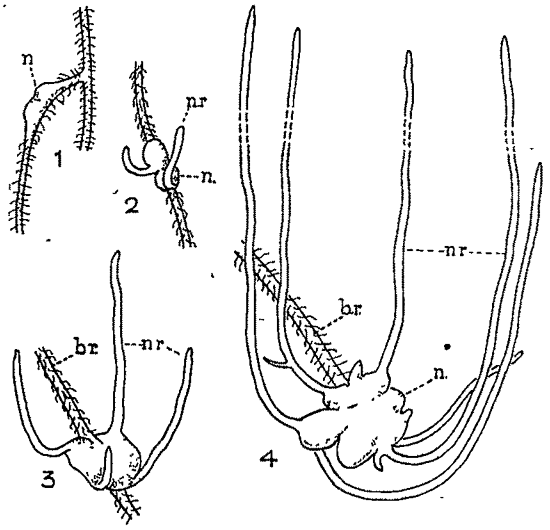
A Feature of the Root Nodules of *Casuarina*

IN the course of an investigation into the development and physiological activity of the root nodules of *Casuarina*, considerable numbers of nodulated plants of *C. cunninghamiana* and *C. equisetifolia* are being grown in water culture. Nodulation was secured by inoculating the roots of young plants with a suspension of crushed *Casuarina* nodules obtained from abroad through the assistance of Dr. H. R. Fletcher, of the Royal Botanic Garden, Edinburgh, and commenced three to four weeks after such inoculation. McLuckie[1] noted a resemblance between *Casuarina* and *Myrica* root nodules in that both show a lobed structure as the result of repeated branching (actually this is true of most non-legume and some legume nodules) and in that a root grows out from each nodule lobe.

An interesting feature which has emerged from the present study is that these nodule roots show strongly upward growth, as illustrated in Figs. 1–4. In some cases the roots (which bear few or no root hairs) have attained a length of 10 cm. and may project from the surface of the culture solution even when originating from quite deeply set nodules. Precisely similar features have been recorded previously for *Myrica gale*[2] growing under a variety of cultural and under field conditions. In that species the upward growth of the nodule roots was shown to be the result of negative geotropism (not of ageotropism, as stated in a recent review[3]), and was thought to be possibly of significance in the ventilation of the nodules, which are otherwise enclosed in a layer of cork tissue. The general position seems to be much the same in *Casuarina*.

It is somewhat surprising that this unusual pattern of root behaviour should be repeated in such unrelated plants as *Casuarina* and *Myrica*, resulting in the nodulated root systems of young plants being virtually indistinguishable from each other externally. A further resemblance is that the nodules of *Casuarina* also are frequently pink in colour. I have no oppor-



Figs. 1–4 show successive stages in the development of nodules and nodule roots in *Casuarina equisetifolia*, orientated as they had grown. *n.* = nodule; *n.r.* = nodule root; *b.r.* = root (with root hairs) bearing nodule. (× 10 approx.)

tunity for examining field material of *Casuarina* nodules *in situ* to ascertain whether the upward growth of the nodule roots is shown under natural conditions. It is probable that such would prove to be the case; but it would be necessary to examine newly formed roots, since the original orientation may no longer be shown in old, moribund roots.

Other observations on *Casuarina* nodules, which according to the work of Aldrich-Blake[4] and of Mowry[5] are nitrogen-fixing, will be presented elsewhere, along with full acknowledgments for assistance received.

Inhibition of Salt Absorption in Red Beet Root Tissue

Rees and Skelding[1] have reported that extracts of red-beet root tissue inhibit the absorption of salts by this material. They claimed that the extracts do not affect respiration, and attributed the influence to a non-metabolic effect on permeability. It was suggested that the inhibitory principle is responsible for natural dormancy in beet roots, and for the inability of freshly cut disks of dormant tissue to absorb salts actively. In an intensive investigation of this problem during the past two years, we have confirmed the main inhibitory effect, and have suggested a probable cause. It is hoped that a full account of the work will be published elsewhere.

In this investigation, the uptake of potassium ions by disks of red beet root tissue has been examined using techniques already described[2]. Rates of respiration were determined in parallel experiments with a standard Warburg apparatus. The tissue extracts were prepared essentially as described by Skelding and Rees. In all cases the potassium content of the experimental solutions and controls was brought initially to 0·02 N, usually by the addition of an appropriate amount of potassium chloride, although occasionally, as indicated below, other salts of potassium were used. A small amount of sodium chloride was added to the control solutions to compensate for the sodium present in the tissue extracts. Competition with hydrogen ions was controlled by bringing all the solutions initially to pH 6, by addition, where necessary, of a small amount of potassium hydroxide. Uptake- and respiration-rates were generally determined over an experimental period of 6 hr. at 25° C.

It may be observed from Fig. 1 that, in the presence of tissue extract, the uptake of potassium was reduced. At the same time there was a considerable stimulation of oxygen absorption. Dilution of the extract caused reduction of the inhibition and a decreased respiratory effect. A similar stimulation of respiration by extracts of red beet has already been reported by Bennet-Clark and Bexon[3]. The absence of an effect in the experiments of Skelding and Rees seems somewhat surprising in view of these observations.

During the present work, the respiratory and salt inhibitory effects of the extract have been separated to some extent by ether fractionation. It has become evident that a large part of the stimulation of oxygen uptake is attributable to sugars, and perhaps other respiratory substrates which do not inhibit salt uptake. On the other hand, fractions of the extract which cause inhibition invariably retain a significant stimulatory effect on respiration. These fractions contain large amounts of organic acids, chiefly malic and citric, which have been separated and identified chromatographically. It is claimed that these are chiefly responsible for the inhibition of ion uptake, and the residual respiratory effect.

The slower uptake of cations from solutions of single salts containing a relatively immobile anion is a well-known phenomenon. Uptake of potassium from a solution containing chloride may be compared with that from a solution of malate from the results in Table 1. Table 1 also shows that potassium uptake in the presence of a tissue extract is inhibited when compared with the uptake from potassium chloride, but not inhibited when compared with the uptake from potassium malate. This is true whether the potassium content of the extract is made up initially by the addition of either potassium chloride or potassium malate. A similar effect has been observed with other organic acids, including citric and succinic acids.

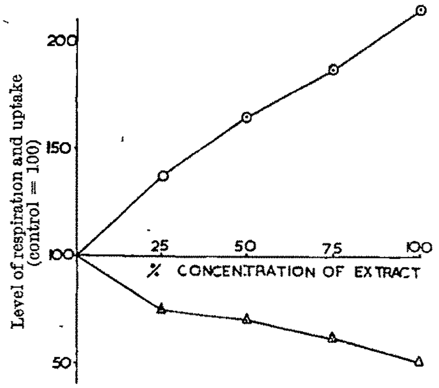

Fig. 1. Effect on disks of red beet root of extracts of the same tissue. Respiration, ○; uptake of potassium, △. 6 hr. at 25° C.

Table 1. Uptake of potassium ions (μequiv. per gm. fresh weight) from solutions of different salts, and in the presence of tissue extracts, in 6 hr., at 25° C.

Solution	Uptake	S.E
Potassium chloride	44·4	± 0·57
Potassium malate	30·9	± 0·07
Tissue extract+chloride	34·4	± 0·26
Tissue extract+malate	29·7	± 0·18

It is concluded that the apparent inhibitory effect of tissue extracts of red beet is mainly attributable to association of a proportion of the cations present with organic anions, which are absorbed more slowly than chloride and cause a retardation in the rate of uptake of cations.

In later experiments we have observed that extracts prepared from actively growing roots of the beet, and also from disks with a strong accumulatory ability, show inhibitory effects on cation uptake which are not significantly different from those exhibited by extracts from dormant roots. These observations indicate that the inhibition is without significance either in relation to the life-cycle of the beet plant, or to the development of an absorptive capacity in tissue disks.

One of us (J. E. D.) wishes to thank the Agricultural Research Council for permission to publish this communication.

Virulent Attacks of Eyespot on Oats

OATS, although known to be occasionally attacked by eyespot caused by *Cercosporella herpotrichoides*, are generally regarded as very resistant to this disease, and hence are usually considered the safest crop to follow wheat or barley where intensive cereal cultivation is being carried on. In view of this statement, the following observations on disastrous attacks of *Cercosporella herpotrichoides* on oats may be of interest.

During a survey of cereal crops in 1955 and the incidence of eyespot in Ireland, numerous crops of oats were reported as badly affected by lodging. A microscopical examination of specimens from eighteen crops confirmed the presence of *Cercosporella herpotrichoides* as the causative agent, the take-all fungus *Ophiobolus graminis* being present in one sample. The lodged crops were widely distributed over twelve counties: in nine cases the number of affected plants was more than 80 per cent, and in some of these the entire crop had gone down; the remaining nine crops had lodged patches of varying extent.

All crops were spring sown, that is, in March or April, and the varieties were Victory, Sun II and Glasnevin Triumph, the rotation being:

1 crop oats, following three successive barley crops;
4 crops, each following three successive wheat crops;
3 crops, each following two successive wheat crops;
4 crops, each following one year wheat after ley;
2 crops, each following one year wheat after roots;
1 crop, the third successive crop of oats;
2 crops, each following wheat, no other particulars;
1 crop, no particulars.

Although typical eyespot lesions occurred to some extent on the oat plants, they were rather scanty; but frequently an indented line was present on one or both sides of the culm. This indentation presented the appearance as if the culm had been pressed in with the thumb-nail, the dent extending up the plant from the base to a height of one to three inches, and sometimes causing a split in the culm. When such stems were cut longitudinally, the fungus was often visible to the naked eye in the central cavity, and, as a rule, more profusely developed than occurred in either affected wheat or barley.

This attack on oats was no doubt closely connected with the prevailing climatic factors. Weather conditions in the autumn of 1954 and the following winter were such as to preclude ploughing. March and April in 1955 were favourable for cultivation, but both May and June were wet. In fact, the last mentioned was the wettest June since 1928 and the nights were unusually cold. Rain fell early in July, but then the weather suddenly changed and came in exceptionally warm, and it continued so throughout August. Lodging of diseased crops commenced towards the end of the third week in July, and as the very warm weather continued, more and more cases were reported. The collapse of the plants was sudden and spectacular on many farms, lodging of most of the crop occurring within two or three days. As no rain had fallen during the previous three weeks in many districts, the occurrence naturally aroused the growers' interest. The various county instructors in agriculture were then consulted, and due acknowledgment is made to them for assisting in this investigation.

In a previous communication[1], Miss Glynne reported a severe attack of sharp eyespot on oats due to *Corticium solani*. We, however, are not aware of any record in plant pathological literature of widespread attacks of ordinary eyespot on oats such as described, and it would seem as if our views on the resistance and liability of oats to *Cercosporella herpotrichoides* will have to be considerably modified.

Spawning of the Sardine at a Definite Time of Day

THE sardine is the principal food-fish of the lands bordering the Adriatic Sea. It is fished only from April to September, since it disappears from the fishing grounds from October to March. This period is the spawning time, when it migrates to regions hitherto unknown. The eggs float in the upper layers of the sea and are therefore found in the plankton. We have now been able to determine the spawning areas by means of systematic plankton studies throughout the Adriatic[1]. In the course of this work, it was found that the sardine (*Sardina pilchardus*) spawns at a certain time of day, namely, in the evening. This is an extension of the finding of Ahlstrom[2] for the Californian sardine (*Sardinops caerulea*). Since the phenomenon seems to be unknown in other marine fishes, we think it worth while to describe our method and results.

Plankton samples were taken hourly for a period of 48 hr. at one spawning place on two occasions.

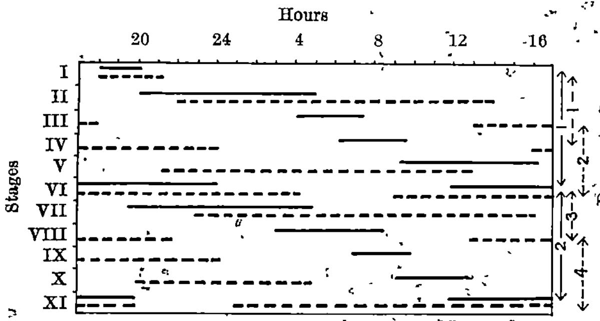

Fig. 1. Duration of embryonic development in the sardine: ———, in December at 18° C.; - - - -, in March at 13° C.

The first occasion was in December and the second in March. These dates were selected because at the place chosen the water temperature is then uniform from surface to bottom: in December it was 18° and in March 13° C. Thus the temperature conditions were as constant as in a laboratory experiment. We made use of the eleven embryonic stages of Ahlstrom, since the development of the two species is similar. Our results are shown diagrammatically in Fig. 1. Hatching takes place after stage XI. It will be seen from Fig. 1 that at 18° C. the duration of embryonic development is nearly two days, and at 13° C. about three and a half days. It is also clear that spawning takes place in the evening.

We have some evidence, deduced from studies of planktonic ova, of the occurrence of spawning at a definite time of day in yet other species of fish, especially pelagic ones, but the data are as yet incomplete. A full account of the work on the sardine will be published in *Acta Adriatica*, volume 7.

Swimming of Fishes

THE 'load carried' by a nursehound *Scyllium catulus* is approximately 5 per cent in this fish, and fishes closely related to it; only 95 per cent of the weight of the fish (in air) is supported by the water. In most teleosts (with swim-bladders), such as the conger, the load carried is about 0·01, or practically the whole of the weight is supported by the water[1].

A large nursehound lends itself to the simple experiment of hanging additional weights on to it and ascertaining how much additional weight it can carry. This was done recently in one of the large outside tanks at the Marine Biological Association at Plymouth, when it was found that a large nursehound could carry an additional weight amounting to practically 25 per cent of its weight in air, while a teleost was practically incapable of carrying anything.

Thus a nursehound has an enormous reserve of carrying power, while most teleosts (with swim-bladders) have practically none.

Nomenclature in Microscopy

SOME confusing terms are used nowadays in microscopy. One repeatedly sees and hears the expression 'light-microscopy' used with the intention of excluding phase-contrast and dark-ground, as though these methods did not involve the use of light. One also notices the expression 'phase-contrast illumination', which is used despite the fact that the essential part of the method occurs at or near the upper focal plane of the objective.

We need a universally recognized word for what is sometimes called 'ordinary' microscopy. The word 'ordinary' is not very suitable, because other methods are coming into wide favour. It might be convenient to speak of 'direct' microscopy in all cases in which (1) there is only one illuminating cone, arranged symmetrically about the optical axis, and (2) the direct and diffracted light are not treated differently. Direct microscopy would be in contrast with 'oblique', 'dark-ground' and 'interference' microscopy.

In 'oblique' microscopy the direct rays are sent through the optical system in such a way that their course is not symmetrical about the optical axis.

In 'dark ground' microscopy the direct rays are either so directed as to miss the lenses of the objective by passing externally to them (external dark-ground), or else they are stopped within or just above the objective (internal dark-ground). What is here called internal dark-ground is commonly called 'central dark-ground'; but the term is not fortunate, for an annular stop is preferable to a central one. ('Dark-ground' seems preferable to 'dark-field', because it is only the background, not the whole field of view, that is dark.)

'Interference' microscopy is also of two main kinds. In one, which may be called 'double-beam interference', two coherent sets of rays are used for illumination. In the other, a single (hollow) illuminating cone is used, and the second set of rays, with which the direct rays will be caused to interfere, originates at the object. This is 'single-beam interference', but the name 'phase-contrast' is (unfortunately) firmly established.

It would be a convenience to limit the expression 'light-microscopy' to cases in which visible light is the illuminant. If one did not state or suggest the contrary, it could be assumed that the illuminant was light. Thus, the unqualified expression 'dark-ground microscopy' would mean dark-ground microscopy with visible light. The various terms suggested in the preceding paragraphs would be (potentially) as applicable to infra-red, ultra-violet and electron-microscopy as to light-microscopy.

It would be consistent to restrict the term 'photomicrograph' to micrographs made with visible light, and thus to speak always of infra-red, ultra-violet and electron 'micrographs'. The expression 'electron photomicrograph', which one sometimes sees in scientific papers, is objectionable.

I thank Mr. W. Galbraith for criticism of the first draft of this communication.

Oxford.
Sept. 28.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 30

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "Hypothermia".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. A. Nizet (Liège): "Hæmopoiesis and General Protein Metabolism".*

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1); at 5.30 p.m.—Mr. Geoffrey Parr: "What Constitutes a Technical Best-Seller?"

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8 30 p.m —Prof. Sir Mortimer Wheeler: "East Africa's Ancient Past" (Mrs. Will Gordon Lecture for 1956).

Tuesday, January 31

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. D. McKie: "Science in Eighteenth-Century Paris".*

Fauna Preservation Society (in the Mappin Terrace Pavilion, Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—General Meeting. Mr. J. A. Hislop: "Some Animals of Malaya".

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5 15 p.m.—Sir Gilbert Rennie: "Recent Developments in the Federation of Rhodesia and Nyasaland".

Society of Chemical Industry, London Section (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—M. Jean Gerard "La Co-opération Technique Européenne" (Jubilee Memorial Lecture).

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p.m.—Mr. A. M. Godridge, Dr. R. Jackson and Mr. G. G. Thurlow: "Industrial Measurement of Gas Temperature".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7.30 p.m —Mr. Edwards: "Laminar Flow Aircraft Design".

Wednesday, February 1

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W C.2), at 5 p m.—Mr. L. L. Hall and Mr. S. G. Young: "Civil Engineering Aspects of Radio Stations' Work".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. J. L. Gillams: "The Harnessing of Nuclear Power for Industry".*

Royal Institute of Chemistry, London Section (joint meeting with the South-West Essex Technical College Chemical Society, at the South-West Essex Technical College, Forest Road, London, E.17), at 7 p.m.—Mr J. S. Hughes and Mr. R. L. Bass. "Silicones—their Manufacture, Application and Analysis".

Thursday, February 2

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p m.—Dr. Mary Whitear· "On Being a Fish".*

Chemical Society (at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m. and 7.30 p m.—Symposium on "Recent Advances in the Chemistry of Colouring Matters".

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4.30 p.m.—Mr. K. H. L. Erhard and Prof. R. G. W. Norrish, F.R.S.: "Studies of Knock and Antiknock by Kinetic Spectroscopy"; Mr. F. J. L. Lipscombe, Prof. R. G. W. Norrish, F.R.S, and Mr. B. A. Thrush: "The Study of Energy Transfer by Kinetic Spectroscopy. I. The Production of Vibrationally Excited Oxygen".

Linnean Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p m.—Mr. E. L. E. Wheatcroft and Mr. H. H C. Barton: "The Potentialities of Railway Electrification at the Standard Frequency".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. J. E. Gordon: "New Ideas in Plastics for Aircraft Structures".

Friday, February 3

British Psychological Society, Industrial Section (in Room 408, Birkbeck College, Malet Street, London, W C.1), at 7.30 p.m.—Informal discussion on Mr. Alec Rodger's British Association paper—"The Effective Use of Manpower". Opening Speaker· Mrs. H. S. Anthony.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m —Prof. H. Munro Fox, F.R.S.: "The Moon and Life".

Saturday, February 4

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Gwynne Vevers: "Life in the Sea".*

British Interplanetary Society (in the York Hall of Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Mr. T. D. Bourdillon: "Portable Breathing Apparatus".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with a good honours degree and teaching experience, and preferably with industrial or research experience) in Physical or Organic Chemistry—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (February 4).

Lecturer (with an honours degree in metallurgy of a British university or equivalent, together with some teaching experience, and experience of metallurgical research or industry) to specialize in the teaching of general and industrial metallurgy—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (February 4).

Superintending Scientist (with a university degree of high standing in physical science engineering or mathematics, and extensive experience in research and development work and in the direction of such work) at the Weapons Research Establishment, Department of Supply, Salisbury, South Australia, to supervise groups engaged in research and development in the fields of electronics, optics and electro-mechanical devices—Senior Representative (AP43) Department of Supply, Australia House, Strand, London, W.C.2 (February 6).

Assistant (preferably with an honours degree in science or agriculture) in the Chemistry Department at Auchincruive, for work mainly relating to the analysis of soil and other agricultural materials—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (February 8)

Lecturer in Genetics—The Secretary of University Court, The University, Glasgow (February 11)

Physicist (with a first- or second-class honours degree or equivalent in physics), at the Ministry of Supply Chemical Defence Experimental Establishment, near Salisbury, Wilts, for research on problems involving optics, heat transfer or radiation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting A.4/6A/AA (February 11).

Senior Scientific Officer (with a first- or second-class honours degree in biochemistry or in a biological subject with subsidiary chemistry, or with evidence of outstanding ability) at the Ministry of Agriculture, Fisheries and Food in London—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S.4549/56 (February 16).

Lecturer in Education—The Registrar, The University, Reading (February 18).

Lecturers (2) in Statistics—The Secretary, The University, Aberdeen (February 18)

Professor of Psychology—The Registrar, University Registry, Oxford (February 23)

Associate Professor in Soil Science at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 25)

Lecturer (with an honours degree in physical chemistry or equivalent qualification) in Physical Chemistry, at the School of Mines and Industries, Adelaide—The Agent General and Trade Commissioner, South Australia House, Marble Arch, London, W 1 (February 27)

Assistant Lecturer or Lecturer in Pure Mathematics—The Secretary and Registrar, The University, Southampton (February 28).

Associate Professor of Soil Science in the Faculty of Agriculture, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (Australia February 28).

Lecturer (preferably with experience in the field of plant physiology with special reference to agriculture, and some training in agriculture as well as botany) in Plant Physiology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (Australia, February 29).

Lecturer (with at least an honours degree in mathematics, and specialized in either pure or applied mathematics) in Mathematics at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia February 29).

Research Fellow in the Department of Zoology and Comparative Physiology—The Registrar, The University, Birmingham (February 29).

Senior Lecturer in Clinical Biochemistry at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 29).

Imperial Chemical Industries Research Fellows in Physics, Chemistry, Engineering, Metallurgy and Pharmacology, or any related subject; three Leverhulme Postgraduate Fellows (two in the Faculty of Science and one in the Faculty of Engineering); and Research Fellows in Nuclear Physics—The Registrar, The University, Liverpool (March 1)

Research Fellow in Botany or in Zoology—The Registrar, The University, Nottingham (March 1).

John Rankin Chair of Geography—The Registrar, The University, Liverpool (March 3).

Assistant Lecturers (2) (one in pure and the other in applied mathematics) in Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 30).

Imperial Chemical Industries Research Fellows in Bacteriology, Biochemistry, Biomolecular Structure, Botany (Plant Biochemistry and Biophysics), Chemical Engineering, Chemistry, Chemistry of Leather Manufacture, Chemotherapy, Colour Chemistry and Dyeing, Engineering (Civil, Electrical or Mechanical), Fuel and Refractories, Geology (including Geochemistry), Metallurgy, Mining (Selective Flotation and Geophysical Surveying), Pharmacology, Physics, Physiology or Textile Industries Chemistry of High Polymers (keratin and man-made fibres), Textile Technology and Wool Textile Engineering—The Registrar, The University, Leeds 2 (April 14).

Imperial Chemical Industries Fellows in Physics, Chemistry, Colloid Science, Biochemistry, Engineering, Metallurgy, PHARMACOLOGY, CHEMOTHERAPY, or related subjects—The Secretary General of the Faculties, The Old Schools, Cambridge (April 30).

ASSISTANT (Grade B) IN PHARMACEUTICS, and an ASSISTANT (Grade B) IN THE DEPARTMENT OF MATHEMATICS at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

CHEMIST/ASSAYER IN THE DEPARTMENT OF GEOLOGICAL SURVEY, Gold Coast Local Civil Service, to take charge of the Geological Survey Chemical Laboratory; to assay ore; to carry out silicate analyses of rocks and minerals; to participate in research in the inter-relation of Gold Coast rocks and in geochemistry—Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.105/13/06.

CHEMIST (with a first- or second-class honours degree or equivalent, and at least three years general industrial experience) at the Central Laboratory, Chiswick—Recruitment and Training Officer (F/EV 550), London Transport, 55 Broadway, London, S W.1.

GENETICIST, Scientific Officer or Senior Scientific Officer grade (with at least a second-class honours degree in botany or other natural science and some years experience in plant breeding and genetics, and preferably experience with tropical perennial crops or maize breeding), at the West African Institute of Oil Palm Research, Nigeria, to carry out research under a senior geneticist in charge of his division, directed towards improving the oil palm by selection and breeding—Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD 197/199/012.

LECTURER IN PHYSICS—The Clerk, Northern Polytechnic, Holloway, London, N.7.

LECTURER IN REFRIGERATION at the National College for Heating, Ventilating, Refrigeration and Fan Engineering—The Clerk to the Governors, Borough Polytechnic, Borough Road, London, S.E.1.

PHYSICAL CHEMIST OR PHYSICIST (with a first- or second-class honours degree or equivalent qualification in physical chemistry or physics), at a Ministry of Supply Armament Research and Development Establishment near Sevenoaks, Kent, for research on initiation of explosive systems and in application to Service stores—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.963/5A/AA.

SCIENTIFIC ASSISTANT (with a good science degree, a reading knowledge of two European languages (of which one should preferably be other than French or German) and ability to write good English), for work in scientific information service involving abstracting and indexing—The Director, Commonwealth Bureau of Soil Science, Rothamsted Experimental Station, Harpenden, Herts.

SENIOR RUBBER TECHNOLOGIST (with a good degree, substantial experience in the rubber industry, evidence of research ability, and eagerness to co-operate with colleagues engaged on basic chemical and physical research), for research and applicational studies in the dry rubber field—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

SENIOR TECHNICIAN IN ZOOLOGY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

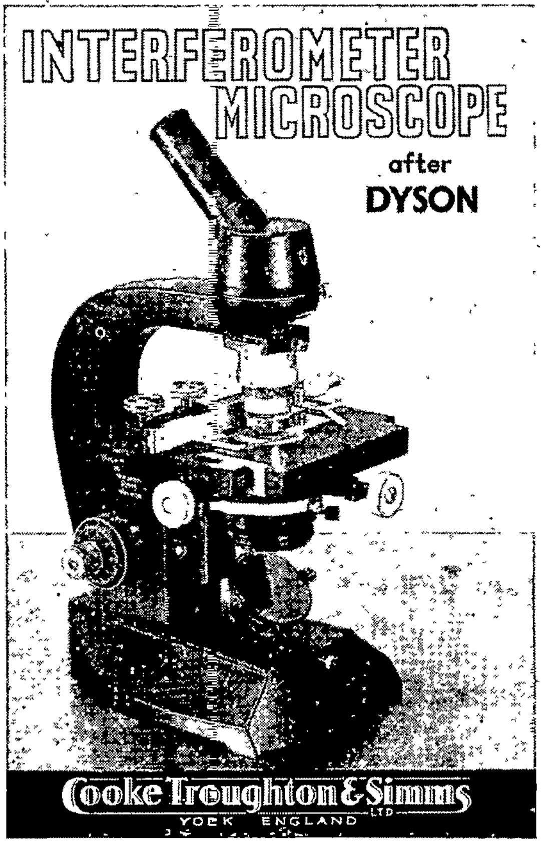
DESIGNERS & MANUFACTURERS OF HIGH VACUUM EQUIPMENT



The Policy for Education

provides a means of saving for a child's education. For example, for a parent aged 35 next birthday,

The Society pays

£100 p.a. for 5 years, beginning in 15 years' time,
and
if the parent dies within 15 years, £100 p.a. in the meantime towards the child's maintenance.

The cost is

£8 7s. 6d. a quarter for 15 years at most.

Enquire for details, giving the ages of parent and child.

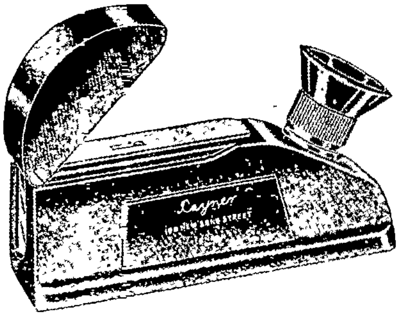
The Equitable Life Assurance Society

(founded 1762)

19, Coleman Street, London, E.C.2.

No shareholders. No commission.

RAYNER REFRACTOMETER



Price: In case with 1.81 fluid, yellow filter and polarizing filter, £15 16s.

Scale 1.30–1.86 in intervals of 0.01. Estimation to 0.001 in white light with filter. Designed for mineralogy, gemmology, routine checks for transparent solids, and for much work with fluids.

LECTURES AND COURSES

GRESHAM LECTURES

Dr. W. H Steavenson, F R A.S. (Gresham Professor in Astronomy) will deliver a course of Four Lectures entitled "Means and Ends in Astronomy" on Mon to Thurs., Jan. 30 to Feb 2, at Gresham College, Basinghall Street, E C.2 Tel. MONarch 2433

The Lectures are free and begin at 5 30 p m

UNIVERSITY OF LONDON

A lecture on "Some Recent Aspects of Diene Synthesis" will be given by Professor K Alder (Cologne) at 5 30 p m, on February 6 at University College (Chemistry Theatre), Gower Street, W C.1.

Admission free, without ticket

JAMES HENDERSON,
Academic Registrar.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

MENTAL HEALTH RESEARCH FUND

Applications are invited for one or more Leverhulme Research Fellowships from suitably qualified persons wishing to pursue full-time research work bearing on problems of mental health, whether in clinical psychiatry or in one of its supporting sciences. Applicants may apply for either a junior fellowship, in the range £700 to £1,200 per annum (including superannuation), or a senior fellowship, in the range £1,300 to £2,000 per annum (including superannuation). The appointments are for two to three years in the first instance, renewable for a maximum of one year thereafter.

Further information from the Secretary, Mental Health Research Fund, 39 Queen Anne Street, London, W 1

SHUTTLEWORTH COLLEGE

LECTURER IN AGRICULTURAL CHEMISTRY

Applications are invited for the above post which will be vacant in April House or board residence.

Particulars from:

J. R. BOND,
Principal

Old Warden Park,
Biggleswade,
Beds.

ADMIRALTY, ROYAL NAVAL SCIENtific Service. Engineers and Physicists (particularly with Electronics) required in Experimental Officer and Assistant Experimental Officer grades in Experimental Establishments in London, Portsmouth, Weymouth areas, Gloucestershire and Scotland Qualifications, British subjects, minimum of higher school certificate (pass degree, higher national certificate or near equivalent an advantage) London salary (men) Experimental Officer £790 to £960 Assistant Experimental Officer £320 10s to £700 (according to age) Appointments unestablished, but opportunities to compete for established posts —Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A214/5A.

ADMIRALTY, ROYAL NAVAL SCIENtific Service. Senior Scientific Officers and Scientific Officers required in Experimental Establishments chiefly in Weymouth and Portsmouth areas and home counties Majority of posts are for Engineers and Physicists (particularly with electronics) Candidates must be British subjects with appropriate first- or second-class honours degree or equivalent high professional attainments Salaries (men) Senior Scientific Officer £1,070 to £1,245 Scientific Officer £513 to £925 (London) Somewhat lower in Provinces All appointments unestablished (with F S S.U), but with some opportunities to compete for established posts.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K) 26 King Street, London, S W 1, quoting A344/5A

COMMONWEALTH of AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF BUILDING RESEARCH

RESEARCH ENGINEER OR PHYSICIST

APPOINTMENT NO. 390/209

Applications are invited from structural engineers, or from persons with similar experience, for appointment to a position as Research Officer at Highett, Victoria The Division of Building Research, has as part of its research programme investigations on the properties and uses of lightweight concrete and gypsum plaster as structural materials These investigations are of considerable importance to the industry in Australia, and should provide detailed information on the physical and mechanical properties of cast gypsum plaster A pilot plant has been constructed involving several novel features, whereby material of known history can be produced. Studies are also in progress on the properties of lightweight aggregates and on the concrete and plaster made from them. Applicants should have a University Honours degree in engineering or science or equivalent qualifications preferably with some research experience. Salary: Dependent upon qualifications and experience, within the range of Research Officer, £A.1,184 to £A 1,730 per annum Initial appointment will be for a period of three years and fares will be paid for the appointee and his family to and from Australia. Should the appointee not wish to return to his home country after the completion of the three-year period, a vacancy may be available for a more permanent appointment. The appointment will be conditional on a satisfactory medical examination.

Applications, referring to Appointment No.: 390/209 and stating full name, place and date of birth, nationality, marital state, present employment, and war service, if any, together with details of qualifications and experience, copies of not more than four testimonials and the names and addresses of at least two persons willing to act as referees, should reach the undersigned not later than February 29, 1956.

W. IVES,
Chief Scientific Liaison Officer.

Australian Scientific Liaison Office,
Africa House,
Kingsway, London, W C 2.

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ZOOLOGY AND COMPARATIVE PHYSIOLOGY

Applications are invited for a Research Fellowship in the Department of Zoology and Comparative Physiology. The salary is £600 per annum, and the appointment will be made in the first instance for one year from October 1, 1956, but is renewable up to a total tenure of three years. Candidates should have reached Ph D. standard, and will be expected to work in one of the following fields of research: Comparative physiology of the neuro-muscular system; or experimental analysis of animal behaviour, or developmental physiology of insects. Research Fellows must be prepared to devote six hours a week to lecturing or demonstrating to undergraduate students

Applications, with the names of three referees, to be submitted to the Registrar, The University, Birmingham, 15, not later than February 29, 1956.

G L BARNES,
Secretary

The University,
Birmingham, 15

MIDDLESBROUGH EDUCATION COMMITTEE

CONSTANTINE TECHNICAL COLLEGE

Principal: G S Atkinson, B Sc, Ph D

Applications are invited for the undermentioned appointments. 1 Senior Lecturer in Metallurgy, to be responsible for courses up to A I M standard and for the development of research in the subject Salary £1,065 by £25 to £1,215. Duties to commence September 1956 2 Assistant Grade B in Mechanical Engineering, to teach up to Higher National Diploma standard Applicants should have a degree or appropriate qualification and experience Salary £525 by £25 to £820 with additions for training and experience Duties to commence as soon as possible 3. Assistants Grade A in: (a) Chemistry; (b) Structural Engineering Salary £450 by £18 to £725 with additions for training and experience Duties to commence as soon as possible

Forms and further particulars are available from Director of Education, Woodlands Road, Middlesbrough, to whom applications should be returned within 14 days of the appearance of this advertisement.

TECHNICAL ASSISTANCE PROGRAMMES AND THEIR SUPPORT

THE fourth annual report of the Consultative Committee for Co-operative Economic Development in South and South-East Asia was published* in Britain about a month after the meeting of the Committee in Singapore. A major issue at that meeting was the decision whether, after the conclusion in 1957 of the first six-year period, the Colombo Plan should continue for a further six years or on an annual basis. On that question the report gives plenty of evidence as to the value of some period greater than one year to enable effective technical and economic plans to be made, without exactly conveying the concern of the delegates over the difficulties resulting from an annual increment of population of 1·6 per cent and the failure of food production to keep pace with this increase in an area already containing one-quarter of the population of the world. The report also provides further background to the report on technical co-operation in the area, issued in August by the Council for Technical Co-operation in South and South-East Asia (see *Nature*, 175, 267; 1955).

On technical assistance the report itself adds but little to the latter report. Progress in this field has matched the progress in economic development in the area, and during 1954–55 more trainees were sent abroad under such schemes and more experts and special equipment supplied to the area than in any previous year, while the amount of technical assistance provided within the area is also increasing. Since the various schemes of technical assistance started, 7,189 training awards have been made and 3,715 experts have been supplied to countries of the area; of these the United Kingdom has made 853 awards and supplied 157 experts. The United States has made 3,025 training awards and supplied 949 experts, and besides utilizing the services of consultant firms in management and engineering, these United States programmes make much use of inter-university contracts, usually for a three-year period, involving interchange of staff between educational institutions in the United States and in the host countries, and also providing training institutions in the United States universities for candidates nominated by these institutions. At the end of August 1955, twenty-three such contracts were in operation in eight member countries, and like other programmes, those of the United States seek to foster activities which can be continued by the recipient country itself. It should be noted also that the United States is now attempting to relieve the chronic shortage of technicians for the Technical Assistance Programme by direct recruitment from the universities.

A feature of the technical assistance programmes of the past two years is the increasing emphasis on the development of training facilities within the Asian countries themselves, and particularly for the middle and lower technical grades. While, moreover, the co-operating governments now have a better idea of what forms of assistance and what type of experts or training facilities the respective agencies can best provide, it is a major and continuing task to ensure co-operation between governments and agencies responsible for technical assistance schemes. Nevertheless, progress is clearly being made, and a sound basis has already been provided on which technical assistance may become of even more significance in the economic development and welfare of the countries of the area in future.

One such direction is nuclear power. It was announced at the Singapore meeting that the United States had offered to establish in south or south-east Asia a centre for nuclear research and training, which will include a research reactor and a small power reactor, and that Canada and India are now working out details of an agreed plan for a research reactor in India. Both establishments will be available also for the use of scientists from other centres. The Canadian delegate announced that Canada would provide Burma with a cobalt beam therapy unit, and that she wished to receive as many Asian scientists as her facilities allowed for research and training in nuclear physics. Afterwards, the United Kingdom and India, as a result of discussions between the Atomic Energy Authority and the Indian Department of Atomic Energy, announced an agreement providing for close co-operation and mutual assistance in developing the peaceful uses of nuclear energy. Members of the staff of the two bodies are to consult and work together on mutually agreed topics, and under the agreement Britain will provide India with enriched uranium fuel for the reactor, offered to India by Canada under the Colombo Plan and now under construction at Bombay.

It is desirable that the magnitude of the assistance which Britain is able to offer in this field should be fully appreciated both in Britain itself and overseas. The reactor under construction at Bombay is intended primarily for research purposes; and in this field Britain is particularly well placed to offer assistance, though in the present man-power situation it is a matter of nice judgment how far that assistance can be given by supplying experts to India or other Colombo Plan countries, as against offering training facilities at Harwell and elsewhere, or exporting nuclear plant. Such developments are as important for Britain's own industrial future as they are for the development of those areas of the world where nuclear energy may well play an essential part if natural resources are to be opened up in step with expanding population.

Nuclear energy is one of the more spectacular aspects of the developments which technical assistance makes possible; but it should be seen in proper perspective, not only in relation to our available resources of materials and man-power, but also to technical assistance generally and Colombo Plan developments as a whole. Perhaps even more than the reports coming from the Consultative Committee for the Colombo Plan, that of the Technical Assistance Board of the United Nations brings out the extent to which technical assistance consists mainly in the multiplication of little schemes rather than in fostering large international projects. From one point of view, the United Nations organization and the Council for Technical Co-operation under the Colombo Plan can be regarded as essentially recruiting organizations for drawing on the experts of the specialized agencies or supporting countries and selecting students from the backward countries to be sent to Western universities and colleges.

---

* Colombo Plan Technical Co-operation Scheme. Report 1954–55. Pp. 30. (London: H.M. Stationery Office, 1955.) 1s. 3d. net.

In 1954, for example, the Technical Assistance Board had 1,584 of its specialists at work in seventy-one countries and made awards to 1,524 Fellows from eighty-six countries. On all this work less than £7 million was spent in 1954, to which Britain contributed £650,000. This share is to be increased to £800,000 in 1956, and at the Singapore meeting Lord Reading emphasized the value which the British Government attached to the technical assistance part of the Plan and indicated that the purpose of the new grant is to increase the British aid to non-Commonwealth countries which have not been members of the Colombo Plan from the beginning and which would not benefit from Colonial Development and Welfare Funds. Moreover, it seems but common sense, where the exchange of experts and provision of training places is so important, to make some reasonable provision for continuity from year to year, so that planning ahead and continuous training are possible. That, and the elimination of as many obstacles as possible to the movement of experts, seem to be the great needs. It is therefore satisfactory to find a disposition on the part of the British Government to lend its support to the idea of continuity, and also to note in the United States some decrease in the difficulty which foreign scholars have experienced in the past in securing entrance visas. Whether or not it is due to the determined efforts of the Federation of American Scientists, which presented a report on the subject last May, no real difficulties were experienced by the participants at the international meeting on arid lands, research and utilization arranged by the American Association for the Advancement of Science last April. Participants were selected entirely for their scientific competence, and, according to *Science*, the State Department co-operated efficiently.

It is at such points as these that the vigilance and help of professional associations can make a valuable contribution to the effectiveness of technical co-operation. Thus it may be recalled that the Federation of British Industries, in a report issued in 1954, emphasized the importance of continuity of budgeting and of giving the fullest possible support that the man-power situation in Britain would permit. Technical assistance is indeed one element for which any expansion in technical and technological education in Britain should provide. Similarly, the improvement of means of communication in scientific and technical matters, whether in the means by which such information is disseminated or in the extent of co-operation between appropriate government departments, is another way in which the provision of technical assistance could be made more effective and the attraction of the indispensable foreign capital made easier. The fourth annual report of the Consultative Committee referred to earlier notes; for example, the establishment of the Ceylon Institute of Scientific and Industrial Research to improve technical processes in industry, to advise on matters affecting the utilization of Ceylon's internal resources, to foster training and the dissemination of technical information, and to co-operate with government departments and the university and other technical organizations in promoting scientific and industrial research.

Where, as in India and Ceylon, such bodies exist and are well staffed and efficiently administered, technical assistance is greatly facilitated. There are, however, wide differences in the technical and administrative standards of the different under-developed countries, as well as in their economic situations. The report emphasizes that, while all the countries in South and South-East Asia depend largely and at crucial points on imports for their development projects, there are wide differences from country to country in such factors as the diversity and stability of exports, the dependence on imports for current consumption, capital inflow or outflow, and the size of reserves in relation to turnover. Again, the countries of the area differ widely in the degree to which they have been able to organize their development. Considerable progress has been made, but all of them face formidable difficulties in collecting the complex technical, economic and financial details on which plans must be based, and creating or expanding the necessary administrative and executive organization.

Largely these are problems of personnel, in which the Technical Co-operation Scheme and other arrangements for technical assistance are invaluable; but in spite of the progress that has been made, this review indicates that the tasks that still remain may well prove even harder, and call for a proportionately greater effort if pace is to be kept with a population increase in the area as a whole estimated at about 10 million persons a year. The review does not encourage facile optimism; it sets the difficulties and problems in the forefront, challenging the sharing of experience in the search for solutions. None the less, it demonstrates that the idea of co-operative effort, both within each country and between countries, is spreading ever more widely and deeply. The British contribution to the Colombo Plan is only a part of a contribution to the development of the more backward areas of which Britain has a right to be proud.

An article on some problems in under-developed areas which Mr. E. W. Golding contributed to the June 1955 issue of *Impact* shows very clearly how closely related are the factors contributing to the effectiveness of technical assistance to those on which scientific and technical advance in general depend. Besides the educational, administrative and like problems which hinder development in the backward areas, there is the exchange of information;

Mr. Golding stresses the vital importance in this connexion of fellowships and studentships which permit free movement of scholars, students, scientists and all kinds of experts from universities and colleges, research institutions and government research stations or laboratories in one country to those in another. It is not simply that the exchange of technique and information is thereby facilitated: international understanding and good-fellowship are likewise promoted; and this can further the better hospitality now afforded the essential foreign capital by most of the Asian countries which are members of the Colombo Plan. The possibilities of agreement on development schemes for international sponsorship are also increased, as Mr. Golding points out, by international meetings such as the symposia organized by the Unesco Advisory Committee on Arid Zone Research in a different area each year. Forums such as these can also assist arrangements for regular exchanges of information on the progress of the schemes and for demonstration visits. What needs to be realized is that scientific, technical and economic data are the indispensable basis for any sound development plan, and that informal as well as official contacts can greatly assist the acquisition of the information needed by the Colombo Plan countries and the backward areas—and even many advanced countries. By pressing resolutely but imaginatively for the removal, as far as possible, of all barriers to the exchange of information, the dissemination of knowledge and the movement of the scholar and scientist and student, the scientist could do something tangible to promote the great purposes for which the Colombo Plan and similar schemes were conceived.

GENETICS AND BRITISH MOTHS

Moths

By Dr. E. B. Ford. (New Naturalist Series: a Survey of British Natural History.) Pp. xix+266+56 plates. (London: William Collins, Sons and Co., Ltd., 1955.) 35*s*. net.

GENERALIZING, this is an excellent book. Its approach is the same as in Dr. E. B. Ford's well-known "Butterflies" in the New Naturalist series, and it is really a sequential volume, there being constant page-references back to "Butterflies". The book is primarily concerned with biological phenomena occurring in the British moth fauna that can be studied and are likely to contribute to the general stream of biological knowledge; it is not a collector's identification book. This is intentional; for, as Dr. Ford states on p. 19, the "entomologist or ornithologist thinks in terms of insects or birds. That was the right way to think when biology was being developed in the past: it is becoming wrong today". This is a curious statement coming from Dr. Ford. So many of the problems that are his concern in the text could only have come to light by means of old-fashioned field-work and the amassing of cabinet collections. Furthermore, the text seethes with evidence that Dr. Ford is himself an extremely active field collector. To bring further problems to light, more collecting will have to be done; surely the ordinary systematic collector might get the status of co-operator and not merely handmaiden. One fears that the latter status is indicated by Dr. Ford's words (p. 19) when he states that he directs "attention to these aspects of the subject which have been neglected in the Lepidoptera, in the hope that entomologists and collectors may be able to supply the data on them which are so badly needed".

A brief chapter on structure and physiology is followed by four chapters on genetics, genetical phenomena and theory, and especially those phenomena seen in wild populations of British moths when these are taken into the laboratory for study or worked on in the field. This is a topic that Dr. Ford has made his own, and these chapters on moth genetics are authoritative. Then follow chapters on polymorphism, on dispersal, and on protective devices. The wealth of illustrative material that Dr. Ford has found in the British moth fauna almost surprises one.

Chapter 8 is a brief intrusion on injurious moths, after which the reader is taken back, through geographical distribution (Chapter 9) and types of habitat (Chapter 10), to relict faunas (Chapter 11), geographical races (Chapter 12) and a most useful chapter on melanism, industrial and otherwise. This last chapter suggests that entomologists should make a serious effort to conduct long-term studies of the moth faunas in the neighbourhood of some of the new industrial centres springing up in Great Britain. Entomologists overseas in the Dominions and elsewhere might do likewise.

The final chapter, on evolution, is again remarkable for the way in which Dr. Ford is able, in discussing this topic, to illustrate it with numerous examples from the British moth fauna. There is an appendix on the classification of moths dealt with in the book. This classification follows, in the main, that of Kloet and Hincks[1], and it is possibly unfortunate that, though more modern, it differs from those of Meyrick[2] and South[3], which are the identification books that readers are most likely to use. There are a glossary of six pages, two pages of references, some distribution maps, and an index that seems to be adequate.

Such criticism as one might level at the book seems, on second thoughts, to be criticism of the editors and, possibly, of an undisclosed lepidopterist whom they may have employed as a sub-editor. On Pl. 20, Fig. 1 is a light-coloured specimen of the great brocade, *Eurois occulta*; Fig. 2 is a dark specimen of the same species. The legend states that the first comes from Rannoch and the second from Essex. In the text, on p. 80, it is correctly stated that the dark form is found in Scotland and the light in the south of Britain. On Pl. 17, Fig. 7, one feels almost certain that the specimen figured is not the silky wainscot, *Chilodes maritima*, as stated.

The colour of inks used in printing the coloured plates should be more carefully controlled by the editors. On Pl. 31 the purple hue on the moths would certainly prevent some of the species from being recognized from the figures. There is an unnaturalness in the green coloration in some places, and the coloration of some of the caterpillars seems a little untrue. An example is the elephant hawk caterpillar (Pl. 21, Fig. 4); but possibly this is in fact a specimen of the greenish form sometimes encountered, though there is no statement in the text or legend that this is so. In the copy before the reviewer, four colour plates (Pls. 6, 7, 18, 19) are off-register: 6 and 18 slightly, 7 and 19 to an extent that makes the subjects very fuzzy. The goat moth caterpillar shown in Pl. 6, Fig. 1, looks moribund, but perhaps it is just getting ready to pupate. The black-and-white photographs are of uniform excellence and make one feel that there is a need to discriminate a little bit in the choice of subjects best suited to colour or to black-and-white photography and reproduction when information is to be conveyed by eye to the reader. Some of the colour figures of small caterpillars tell one very little indeed.

There is no point in combing the text for trivial errata; but one cannot help wondering how the author, or the editors, at least two of whom are well versed in general taxonomic theory, allowed the family Lasiocampidae (the eggars) to stray out of the super-family Lasiocampoidea into the next super-family Bombycoidea, though they might be forgiven for not realizing that the Endromididae (*sic pro* Endromidae) of the super-family Bombycoidea were out of place in the super-family Lasiocampoidea (p. 237).

AN INTRODUCTION TO PRECAST CONCRETE

Precast Concrete

By Dr. Kurt Billig. Pp. xvi+341. (London: Macmillan and Co., Ltd., 1955.) 32*s*. net.

THE art of precasting concrete has given rise to an established industry producing staple things like blocks, tiles, floor beams and parts for small structures, where problems are in the nature of factory production-engineering, and a more nebulous practice involving the more sophisticated extension of the art to large structures, bridge girders, and so on, which demand the designer's closest attention if the choice of the medium is to be economically justifiable. The whole industry has been profoundly affected within the past decade by the technique of prestressing, which has developed into a competitor with structural steel.

To deal with the whole subject in a comprehensive manner would demand a writing of considerable dimensions. Dr. Kurt Billig has mentioned most aspects of precast concrete: those forming the basis of organized industry are treated summarily, and attention is given chiefly to the structural uses of reinforced and prestressed precast concrete. In attempting to cover so large a field in a book of about three hundred pages, it is not surprising to find that frequently the treatment is hurried. The aim appears to be the stimulation of interest in the potentialities of structural precast concrete, rather than to present a text-book for the factory engineer or designer. Some 40 per cent of the material has appeared elsewhere; almost the whole of Dr. Billig's earlier work, "Structural Precast Reinforced Concrete", published by the Cement and Concrete Association in 1947, has been reproduced with scarcely any alteration, except that the sections have been re-shuffled to suit the larger work. Dr. Billig has also drawn on his book, "Prestressed Concrete".

The book is divided into four parts: Part 1 deals with design and production; Part 2 with the precast units themselves; Part 3 with joints; and Part 4 with structures in which precast concrete has been used. One might expect difficulties in avoiding overlapping with this breakdown of the subject, but on the whole Dr. Billig handles his matter satisfactorily. There are some cases of repetition, however, and occasionally the meaning becomes elusive, as, for example, "The work done during prestressing levels the discrepancy between the absolute values of the compressive and tensile resistances of the concrete and between the ultimate strains in tension of the steel and the concrete". One or two points seem to receive disproportionate attention: a discussion on 'æsthetics' labours the old problem whether concrete, which looks like stone, can rightly be placed in a position of tension, and six systems are described which use concrete spread on hessian or jute fabric.

References are quoted at the ends of a number of chapters, but Dr. Billig has chosen not to annotate the text in any way to indicate what he may have drawn from these works. This is unfortunate since, for many readers, it defeats the object of such references.

Dr. Billig is at his best when writing about industrial structures, and one wishes that he had gone into greater detail and given more examples. Many of the examples invite the comparison of precast reinforced concrete with *in situ* concrete. In his chapter on "Efficiency", Dr. Billig has attempted to indicate that the assessment of prestressed concrete should be by comparison with structural steel. That there is a place for both normally reinforced and prestressed precast concrete in the scheme of things seems to have been demonstrated, but what is best done by one or the other does not emerge at all clearly.

T. WHITAKER

ZOOLOGICAL LITERATURE OF 1952

The Zoological Record

Vol. 89 (Being the Records of Zoological Literature relating chiefly to the year 1952). Edited by G. Burder Stratton. Pp. vi+1450. (London: Zoological Society of London, 1955.) 120*s*.

ZOOLOGISTS throughout the world owe a special debt of gratitude to the Zoological Society of London for continuing to produce each year the "Zoological Record". Its compilation is a very heavy task and the general editor, Mr. G. Burder Stratton, and the sectional editors and recorders, in preparing the lists of titles of all zoological publications appearing during the particular year under consideration, have to search through hundreds of scientific periodicals in all languages. In addition, the material is classified so as to be of use not only to taxonomists, but also to those engaged in any of the many specialist branches of the subject, such as structure (including histology and cytology), physiology, evolution and genetics, development, reproduction and sex, ecology and habits, geographical distribution, and palæontology and geological distribution. The amount of time saved by having this information thus summarized by specialists in the subjects can only be fully realized by those who have tried to search through the literature on any particular group of animals, or species, previous to 1864 when the "Zoological Record" was founded.

The present volume relates chiefly to the literature of the year 1952, but unfortunately does not include the sections dealing with Vermes and Trilobita, which did not arrive in time. It is hoped, however, that the literature for both 1952 and 1953 of these two groups will be included in Vol. 90.

The other sixteen sections give a rough indication of the work going on in different groups of the animal kingdom, and, as would be expected, Insecta heads the list with a total of 3,332 titles. The next largest section is Aves with 1,696 titles, and other large groups include Mammalia, 1,282; Protozoa, 1,194; Pisces, 1,115; Amphibia and Reptilia, 1,090; and Mollusca, 968. Finally, there is a section giving a list of 1,883 new generic and subgeneric names recorded during 1952, which is made up as follows: Protozoa, 94; Porifera, 12; Coelenterata, 86; Echinoderma, 26; Brachiopoda, 22; Bryozoa, 51; Mollusca, 140; Crustacea, 50; Arachnida, 139; Insecta, 1,107; Protochordata, 1; Pisces, 75; Amphibia, 7; Reptilia, 29; Aves, 2; Mammalia, 42.

It may be recalled that in 1954 the Zoological Society of London authorized a reprinting of Vols. 1–20 of the "Zoological Record", which had been out of print for many years. The success of this venture has been such that the reprinting of further volumes which have become out of print is now under consideration, and any such issues would be welcomed by all zoological libraries and departments with incomplete sets of this invaluable publication.

EDWARD HINDLE

COLORIMETRIC METHODS IN CHEMICAL ANALYSIS

Colorimetric Methods of Analysis, including Some Turbidimetric and Nephelometric Methods

By Dr. Foster Dee Snell and Dr. Cornelia T. Snell. Vol. 3, Organic—1; pp. viii+606; Vol. 4, Organic—2; pp. vii+676. Third edition. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953–54.) 93*s.* 6*d.* net each vol.

THE authors of this well-known treatise on colorimetry have set themselves an almost herculean task in producing a third edition. The organic and biological material covers such a wide field that it has necessitated two volumes instead of the single volume originally contemplated. Vol. 3 comprises nineteen chapters commencing with a very brief but important introductory one, which explains that "every possible method of condensation has been applied" in order to include such a large number of individual substances. The division of this wide variety into logical sequence and chapters has been difficult. Whereas all the hormones are dealt with in a single chapter, it has been found necessary to spread the vitamins between the two volumes in six chapters. This difficulty also applies to pigments, weed-killers, insecticides and plant growth-regulating substances. In order to make easy reference to a given compound, each substance in the subject index is listed as far as possible both under its systematic name and also its trade or recognized trivial name.

Several methods are sometimes described for one substance, depending on the need to determine milligram or microgram quantities. The authors have described, as far as possible, the substances known to interfere with a particular determination and have included methods for their removal. The nineteen chapters include hydrocarbons, alcohols, esters, phenols, the sugar and glucoside family, aldehydes and ketones, the acid family (except amino-acids), sulphur and halogen compounds. Where such a wide field has been covered it seems unjust to want more; but I, and no doubt others too, regret that a little space could not be found for some important subjects. In the chapter on alcohols and their esters, it is disappointing that more space has not been found for the determination of alcohol in blood and urine, as this subject has assumed much medico-legal significance in recent years.

Glycerol, in view of its commercial importance, seems worthy of fuller treatment. On the other hand, sixteen pages have been devoted to thiamine (vitamin B_1), since the vitamin may occur in so many materials, including pharmaceutical products, foods and biological specimens. There are no less than fifty-eight references to the literature for this one substance. Similarly, sulphonamides, which have assumed such prominence in medicine, have been allocated thirteen pages and seventy-three references. For the sake of completeness, methods which are scarcely colorimetric have been included; for example, in the section on fats and oils, the conjugated and non-conjugated constituents of fats and oils are determined by an isomerization method, and readings taken by spectrophotometer in the ultra-violet region. Included in the chapter on halogen compounds are some of the more important insecticides and their determination in foods, milk, biological tissue and spray residues. While the specialist in this subject will need more information than can be given in such a general treatment, the authors are to be congratulated in collecting such a wide range of references.

Vol. 4 deals almost entirely with naturally occurring substances in its sixteen chapters. These range from amines and amino-acids to sterols, hormones, alkaloids, enzymes, antibiotics and pigments. Methods for the determination of quaternary ammonium compounds and domestic and textile detergents in effluents and sewage would have been welcomed by water consultants, since the presence of these substances constitutes an increasing difficulty in water purification. The final chapter describes methods for the measurement of the colour of liquids. The authors have confined themselves almost entirely to methods adopted by the Association of Official Agricultural Chemists, the American Public Health Association, and the American Oil Chemists Society. This is logical for American readers, but others may require more general methods. As stated in Vol. 1, the authors considered the use of the C.I.E. system of colour measurement outside the scope of their treatise, but it is hoped that a wider use of the system will merit its inclusion in a future edition.

In the four volumes of the complete work a surprising variety of materials and methods has been dealt with, and very few which reach the consultant omitted. This greatly enlarged edition should find a place in all laboratories using colorimetric methods of estimation. Although the specialist in each subject is unlikely to find methods which are new to him, the four volumes contain the most complete collection of colorimetric determinations I have yet encountered. The volumes are well printed and illustrated and are reasonably free from misprints, and the index to each volume is full and carefully prepared.

J. KING

Primates

Comparative Anatomy and Taxonomy, 2: Haplorhini: Tarsioidea. A Monograph by W. C. Osman Hill. (Edinburgh University Publications—Science and Mathematics, No. 3.) Pp. xx + 347 + 14 plates. (Edinburgh: At the University Press, 1955. Agents: Thomas Nelson and Sons, Ltd.) 63*s.*

DR. W. C. OSMAN HILL has lost little time in bringing out the second part of his monumental review of the Primates, of which the first, on the Strepsirhini, was published in 1953 (see *Nature*, 172, 880; 1953). The present volume deals with the Tarsioidea, which Osman Hill, following Pocock (but contrary to Gaylord Simpson), accepts as a sub-order of the Haplorhini. This division of the Primates also includes the sub-order Pithecoidea, comprising the monkeys, apes and man. Osman Hill appreciates that the Tarsioidea differ considerably in many parts of their anatomy from the Pithecoidea, but justifies his acceptance of the earlier classification by appealing to the difficulty of classifying *Tarsius* with the lemurs.

The volume is essentially a monograph on *Tarsius spectrum*, but begins with a general review of the literature on the systematic anatomy of the Haplorhini, which includes some observations on reproductive physiology and behaviour. The middle section of the book, some hundred and thirty pages long, deals specifically with the anatomy of *Tarsius spectrum*. This part of the work incorporates a number of original observations. The final sixty pages or so summarize what has been published about the palæontology of the sub-order. The book is well illustrated.

In a review dealing with a field as wide as that which Dr. Osman Hill is trying to cover, it is inevitable that some literature should be overlooked and that reference to certain authoritative views should be lacking; such omissions are especially evident in the section dealing with the general biology of the Haplorhini. In view of the limited amount of our knowledge, it is also not surprising that the section dealing with the embryology, psychology and reproductive physiology of *Tarsius spectrum* occupies only fifteen pages as compared with the hundred or so devoted to its anatomy. Disproportions of this kind are a challenge to future workers. Dr. Osman Hill's work is sufficiently encyclopædic to serve, like the volume which preceded it, as a reference book and summary for all future students who are likely to concern themselves with the phylogenetically important group of Primates which *Tarsius* represents.

S. ZUCKERMAN

A Textbook of Radar

Edited by Dr. E. G. Bowen. (A Collective Work by the Staff of The Radiophysics Laboratory, C.S.I.R.O., Australia.) Second edition. Pp. xiii + 617 + 41 plates. (Cambridge: At the University Press, 1954.) 45*s.* net.

THIS second edition of a collection of articles on various aspects of radar by the staff of the Radiophysics Laboratory of the Commonwealth Scientific and Industrial Research Organization, Australia, is now published by the Cambridge University Press, under the editorship of Dr. E. G. Bowen. The book deals with the fundamental principles of radar, and its application to war, to navigation and to various problems of physical science. In the first two of these, the present edition does not differ greatly from the first, though the section on military applications has been curtailed. The section on application of radar to physical science has been expanded and now deals with such topics as ionospheric research, moon echoes, meteor trails, meteorology and radio astronomy. This is a welcome addition which helps to bring the subject up to date as regards non-military applications.

The book succeeds in compressing into a single volume a large amount of material, but is still quite readable by the beginner. As editor, Dr. E. G. Bowen has brought a certain amount of unity into what might have been just a collection of papers. Clearly, it cannot replace the specialist volumes on war-time radar research issued by the Radiation Laboratory in the United States or the Modern Radio Techniques Series published by the Cambridge University Press, but will serve as an excellent introduction to these. The practice of the first edition of quoting unpublished reports has fortunately been discontinued to a large extent, and many more references to published work are given. The index of authors is, however, very inadequate for a work of this sort, which should prove valuable for reference as well as for initial instruction.

R. A. SMITH

Frontier to Space

By Eric Burgess. Pp. xvi + 174 + 26 plates. (London: Chapman and Hall, Ltd., 1955.) 21*s.* net.

IN "Frontier to Space" Mr. Eric Burgess gives a survey of recent research on the terrestrial upper atmosphere, paying special attention to the results obtained with the aid of rockets. Most of these results were reported at the conference held in Oxford in the summer of 1953 under the auspices of the Gassiot Committee of the Royal Society. Though they have been published in full in "Rocket Exploration of the Upper Atmosphere" (Pergamon Press, Ltd., London) the summary presented by Mr. Burgess is to be welcomed. Sufficient detailed references to the original literature are given to make the book a useful introduction to the subject. Many interesting and instructive diagrams and plates are included.

The student must not accept all that is said uncritically, for the author sometimes quotes out-of-date views. For example, it is misleading to state (p. 79) that "The growth and decay of the ionized atoms and molecules [in the ionosphere] causes a glow to be emitted which appears as the day and night airglows"; or to state (p. 82) that "It is nowadays thought, therefore, that the ionization of oxygen is the most likely mechanism [for the production of *D*-region ionization]". In spite of occasional defects of this nature, the book can be recommended. The educated scientific public should be able to read most of it without difficulty and should find it stimulating. The production is excellent.

D. R. BATES

The Theory of Stereoscopic Transmission and its Application to the Motion Picture

By Raymond and Nigel Spottiswoode. Pp. xii + 179. (Berkeley and Los Angeles: University of California Press; London: Faber and Faber, Ltd., 1953.) 42*s.* net.

AMONG the most popular items at the 1951 Festival of Britain were the three-dimensional films shown at the Telekinema. A year or two later, 3D had taken the film industry by storm, and we became familiar with 'Polaroid' viewers, eye-strain, some curious space distortions and, from time to time, some quite remarkable and beautiful stereo-cinematic effects. All this has now vanished, and we are left with wide-screen techniques instead.

During these years the Spottiswoode brothers were the leading enthusiasts in Great Britain, and they give in this book an account of the theory of stereoscopic cinematography in a form which they have found by experience to be most helpful. Perhaps some people may be surprised to learn that anything serious in the way of a theory is required—Hollywood was probably taken by surprise too—but the presentation of a set of mutually consistent three-dimensional clues is no easy task.

In addition to elaborating the geometry of the binocular parallax, the book deals with the characteristics, mechanisms and methods of practical stereoscopic systems. Neither the algebra nor the terminology which the authors have used makes the book easy reading—terms like hyper-infinite and hypo-infinite systems seem designed to confuse rather than clarify the problem—yet if only the film industry could have spared the time to master the subject instead of impetuously rushing ahead, something really exciting might have emerged. The possibilities are still there.

W. D. WRIGHT

Practical Physical Chemistry

By Prof. Alexander Findlay. Revised and Edited by J. A. Kitchener. Eighth edition. Pp. xiii+364. (London: Longmans, Green and Co., Ltd., 1954.) 18*s*. net.

PROF. A. FINDLAY'S book has been a friend to teachers and students of physical chemistry for many years. It was first published in 1906 and has now reached an eighth edition. With the passage of time new interests and techniques have arisen, and books must take account of these. Dr. J. A. Kitchener has undertaken a revision which is intended to preserve the original character and at the same time bring the book up to date. Many new experiments and apparatus for performing them are described. References to literature are given at the ends of the sections.

The error of some books of this kind of giving large digressions on theory, and sketchy mentions of experiments which cannot be performed in the average student laboratory, is avoided, and the text is studiously devoted to practical work, the equations necessary for the calculation of the results being provided. In this way it has been possible to include a large amount of material—more than can be attempted in the usual practical course but giving a choice of work.

The book is an excellent guide to practical physical chemistry for the honours student, and research students should find it of great service. The revision has been very well done; and with its type reset and new figures provided, the volume is very handsome and worth double the price at which it is sold.

Birds of Eastern and North-Eastern Africa

By C. W. Mackworth-Praed and C. H. B. Grant. (African Handbook of Birds—Series 1, Vol. 2.) Pp. viii+1099+plates 54–96+photographs 7–19. (London: Longmans, Green and Co., Ltd., 1955.) 45*s*. net.

AFTER an interval of three years, this useful and excellent work has been completed by the issue of the second volume, on the same lines as its predecessor (see *Nature*, 172, 92; 1953). Among other things, one notes again with pleasure the marginal drawings and distribution maps; and the standard of reproduction of the colour plates has been much improved. The lithographed text, as before, gives the essential facts about identification, range and habits for each species and race; and there are keys to the different groups. The volume covers the passerine birds, and the number of represented forms makes it even larger than the first; the weavers occupy more than a fifth of it.

In an introductory note to this volume, the authors make a point which needs to be stressed on every suitable occasion. They refer to the many missing facts about habits, habitat and breeding which field observers have the opportunity of filling in: "It is, however, essential that they should be published. We know of many cases where such biological data are known to local residents but to no one else". This work should be a great stimulus, throughout East Africa, to the making of such observations and to recording them as contributions to available knowledge.

LANDSBOROUGH THOMSON

The Genus Nicotiana

Origins, Relationships and Evolution of its Species in the Light of their Distribution, Morphology and Cytogenetics. By Prof. Thomas Harper Goodspeed. (Chronica Botanica, Vol. 16.) Pp. xxii+536+118 plates and illustrations. (Waltham, Mass.: The Chronica Botanica Company; London: Wm. Dawson and Sons, Ltd., 1954.) 12.50 dollars.

A FEATURE of agricultural botany to-day, in both warm and temperate climates, is the intensive study that is often given to all the members of any genus that happens to contain crop plants or economic plants of some kind. How valuable this kind of work can be has been well demonstrated with the potato.

The appearance now of a most comprehensive monograph of the genus *Nicotiana*, to which tobacco belongs, is therefore very much to be welcomed. These investigations on the genus *Nicotiana* have been carried out by Prof. T. H. Goodspeed at the University of California Botanic Garden during the past thirty years and were actually initiated even earlier (in 1904). Of the sixty species known to belong to the genus *Nicotiana*, no less than fifty-six were cultivated in the Botanic Garden—a fine achievement. Five different expeditions were made to South America, and these accounted for a good deal of the living material. Actually, only two species, *N. tabacum* and *N. rustica*, are of direct economic value or yield commercial smoking tobacco at the present time. In its original distribution, before being spread by man, the genus was more or less restricted to the Americas, with a few species in Australia and some islands of the Pacific.

The author divides his monograph into six parts, the first part dealing with distribution, while successive parts deal with morphology, cytology of species, cytology of F_1 interspecific hybrids, phylesis (or evolution) and taxonomy of *Nicotiana*. Full descriptions, accompanied by line-drawings, are given for each of the sixty species. In the sections on cytology, karyotypes of all but four species and complete meiotic sequences in representative species and hybrids are illustrated. The work is a good example of modern treatment in speciation and probable evolution in plants. It should be of special interest to botanists and geneticists and to many others engaged on scientific work with tobacco or the related species.

BRITISH NUCLEAR ENERGY CONFERENCE

INAUGURAL MEETING

ON November 30, Sir Christopher Hinton, managing director of the Industrial Group, United Kingdom Atomic Energy Authority, opened the inaugural meeting of the British Nuclear Energy Conference by recalling that, although the first six years of the British atomic energy project were devoted to military requirements, a nuclear industry is now emerging. Success in this field depends upon the ability to develop and adapt existing techniques, and it was thought better that the Institutions of Civil, Mechanical, Electrical and Chemical Engineers and the Institute of Physics should jointly organize the British Nuclear Energy Conference as a permanent body for providing a forum where nuclear developments can be discussed rather than set up a new and independent society for this purpose.

Sir John Cockcroft, director of the Atomic Energy Research Establishment, gave the opening lecture, which was on "The U.K. Atomic Energy Authority and its Functions", and said that during the past three years it has been possible to turn an increasing part of the efforts of the Authority's Research and Industrial Groups to the development of nuclear power. He recalled that the Government White Paper, "A Programme of Nuclear Power", anticipated that by 1965 it might be possible to commission on a commercial basis more advanced (Stage II) reactors than the gas-cooled ones with which the programme is being started. Studies have been made of the pressurized light-water reactor and of the sodium–graphite reactor. Within the limits of the present uncertainties, there is little to choose between them on economic grounds. A choice will therefore have to be made on other grounds, since the present feeling is that the Authority's resources are adequate for the development of only one Stage II reactor in addition to the work already in hand on the fast reactor for Stage III of the programme. Development of the fast reactor will take a long time and is unlikely to make any significant contribution to electricity supply until the 1970's.

Development of a new type of reactor commences with a feasibility study by a team of physicists and engineers working with chemists and metallurgists. If the reactor is feasible, it is followed by a design study at which stage sub-critical or just-critical assemblies are built to ascertain nuclear data, and testing loops are arranged in research reactors to obtain technological data. Such a study may easily cost £300,000 a year. The annual value of isotopes produced by the Authority is now about £400,000, and this activity will be extended by the preparation of mega-curie sources from fission-fragment cæsium and strontium. These have a potentially wide field of industrial use, and their application to the polymerization of ethylene to polyethylene is already well known. A Technological Irradiation Group has been formed at Harwell to assist industry in studying these possibilities.

V. A. Pask, the chief engineer, and J. C. Duckworth, the nuclear power engineer of the Central Electricity Authority, followed Sir John with a lecture on "The Place of Nuclear Energy in United Kingdom Power Development". They pointed out that of all the countries interested in nuclear power, none has quite the same need for its quick commercial development as has Great Britain, since it is now clear that a rapidly increasing proportion of the nation's energy requirements must be supplied either from imported coal or oil or from nuclear fission. Future plant requirements were surveyed in the paper on the basis that home-produced coal for electricity might reach a maximum of 60 million tons a year by 1970 and thereafter remain at that level, and arrived at the conclusion that the nuclear capacity required to avoid import of fossil fuel would rise from 3,900 MW. in 1965 to 23,000 MW., or rather more than the present total plant capacity, by about 1980. It was noted that 3,900 MW. by 1965 is about twice the capacity proposed in the White Paper for that year, and arrangements have already been made to burn oil equivalent to about 8 million tons of coal as a stop-gap measure. The capacity of coal-fired plant must be expected to continue to rise, and by 1980 might still be nearly two and a half times the nuclear capacity. By 1980 the nuclear plant might well be carrying the whole of the base load or continuous demand.

The costs of electricity from nuclear power plants are subject to many uncertainties, not least of which is the length of time a fuel element may be left in the reactor before it must be withdrawn for re-processing. Nevertheless, Mr. Pask and Mr. Duckworth, after a detailed consideration, have come to the conclusion that it is a reasonable expectation that net generation costs per kilowatt-hour from the earlier nuclear plants should be comparable with those from the most advanced coal-fired plants.

The prospect of competitive nuclear power with low operating costs means that this plant will carry the base load and that eventually the whole of the conventional plant will be required to operate on one- and two-shift cycles. Thus the Central Electricity Authority and the manufacturers of the conventional plants are faced with the problems of providing full operational flexibility in the large sets with advanced steam conditions which are essential if maximum economy in both capital and operating costs is to be achieved. The alternative approach is to improve the load factor. If, in the long run, nuclear power provides cheaper electricity, it should permit more attractive night tariffs than are possible at present, but a radical change is unlikely unless solutions can be found to the social problems involved in the wide adoption by industry of shift working. The fact that there would be an enhanced case for pumped-storage schemes was explained.

Nuclear plant will tend to be sited in areas where insufficient coal is mined to meet local requirements and as near as possible to major load centres. The electrical system in Britain as planned before nuclear energy became a serious proposition involves the transmission of some electricity from the coal-producing Midlands to the load centres in the south. It follows from the base-load operation of nuclear plant that transmission of electricity generated from coal will be impossible at a high load factor and therefore uneconomic. The transmission capacity now being provided for this purpose will, as time goes by, be absorbed as inter-connexion capacity for the pooling of spare plant.

A. S. McLean, medical officer of the Industrial Group of the Atomic Energy Authority, and W. G. Marley, head of the Health Physics Division at Harwell, in their lecture on "Health and Safety in a Nuclear Power Industry", set out to put this aspect in its proper perspective. The early approaches to this subject may now seem timid and full of unrealistic apprehensions, but at the time they were perfectly justified in view of the unfortunate history of radiation in occupational disease.

Radiation injuries are often grave and are seldom reversible by treatment, but the doses causing injury are now quite well known. The workers in the Atomic Energy Authority show no abnormalities, there has been no case of radiation injury, and no new disease has made its appearance among them. In fact, no disease is peculiar to radiation. Causes cannot be determined clinically, and statistical methods are clearly necessary should questions of liability arise. The direct experience of the atomic energy project in Great Britain now extends over nearly a decade, and there has come with it a feeling of reasonable confidence that, given proper attention to adequate safeguards, work in the nuclear power industry is as safe as work anywhere else.

H. J. Grout, head of the Reactor Engineering Division at Harwell, emphasized in his lecture on "The Use of Research Reactors in Nuclear Power Development" that there is no broad background of experience yet available to guide engineers in the specification and design of nuclear power reactors. They must rely on the results of theoretical calculations and laboratory experiments, and the opportunities for subsequent inspection, repair or modification are strictly limited once the reactor has been at power and the internal structure has been intensely radioactive. It is therefore of paramount importance to ensure that the industry is backed by adequate research facilities. The purpose of research reactors is to provide both the radiation field and test-bed facilities to enable the behaviour of reactor materials and components to be studied and tested under simulated operating conditions and to obtain fundamental information in the fields of reactor physics, chemistry and metallurgy. On the fundamental side, he instanced the determination of neutron cross-sections of the various fissile materials, the metallurgical investigation of radiation damage, and the study of the effect of radiation on the rate and the equilibrium conditions of chemical reactions.

The direct application of some of the foregoing to practical designs is not easy, because many problems are so complex that the behaviour of specific systems and complete components must be studied under operating conditions. An 'active hot loop', which is an experiment on an engineering scale, would consist of a number of prototype fuel elements in a coolant system, built into an experimental hole in a reactor such that the neutron flux-level in the region would cause the elements to operate at their designed rating. A serious technical limitation of research reactors is that it is impossible to carry out accelerated tests on fuel elements without radically altering many factors which contribute to their failure.

For certain neutron cross-section measurements, a low-power reactor of stable characteristics is needed, and the pile at Harwell known as GLEEP satisfies this need. The pile BEPO at Harwell provides facilities for matters not directly connected with the power programme, such as isotope production and studies of biological systems as well as much fundamental and technological data. Its low flux ($1{\cdot}5 \times 10^{12}$ neutrons/cm.^{2}/sec.), however, limits its field of application to technological investigations. To provide the necessary facilities at a flux of 10^{14} neutrons/cm.^{2}/sec. three enriched-uranium heavy-water-moderated and cooled reactors are under construction. The piles DIDO and PLUTO will be at Harwell, and another PLUTO will be constructed at Dounreay. Each will be equipped with associated 'hot' laboratories for the examination of irradiated specimens. The rent of experimental facilities in DIDO may vary from £100 a day down to £10 a day for those in less-attractive low-flux positions.

In the discussion, emphasis was laid upon the magnitude of the task ahead both by Mr. J. Eccles, deputy chairman (operations) of the Central Electricity Authority, and by Mr. A. L. G. Lindley, of the General Electric Co., Ltd., who stressed the problem of finding sufficient men with suitable qualifications for work in this field without making undue sacrifice of effort on other work in the electrical industry. There was no suggestion from any quarter at the meeting that the problems can be regarded in any light other than that of difficulties which must be faced and overcome and it is fitting to conclude this article with the sentiments expressed by Sir Claude Gibb, chairman of the Nuclear Power Plant Company, that it is quite certain that we can, and must, meet the nuclear power programme if Britain as we know it to-day is to survive.

THE MORPHOLOGY OF LARGE-CHAIN MOLECULES*

By Prof. CH. SADRON

University of Strasbourg, and Director of the C.N.R.S. Centre for Research on Macromolecules,
6 rue Boussingault, Strasbourg

SINCE the work of Staudinger some thirty years ago, followed by that of a few pioneers such as H. Mark, K. H. Meyer, W. Kuhn, and others, it has been established that the concept of a molecule can be applied to assemblies of atoms of ever-increasing complexity, ranging from the single atom of the rare gas molecule to hundreds of thousands of them. In fact, it is now known that there is no upper limit to the mass and dimensions of molecules: a crystal of diamond, or a piece of vulcanized rubber, can consist of one single enormous molecule.

Yet, although the notion of the molecule remains constant throughout this vast range, as the assemblies of atoms become more complex so they assume progressively new properties. For example, the substances which they make up do not have such well-defined properties: they cannot exist in the gaseous state; they are not thoroughly crystallizable; and their physical and mechanical properties in the solid state are new, complex and delicately balanced. All the same, new problems arise and new methods of investigation are required for the description of giant molecules. In the case of a molecule containing a very few number of atoms, it is possible to describe exactly the relative mean positions of their nuclei, their vibrations and even sometimes the probability distribution of the electrons which bind the atoms together.

---

* Substance of a lecture given in the University of London on November 7.

The use of quantum mechanics and of such techniques as spectrometry with radiation ranging from X-rays to microwaves, and even the use of proper chemical methods, generally suffice. As the number of atoms included in the molecule becomes larger, it appears that we have to describe the relative positions of atoms at larger distances, and we have to consider two steps in our investigation. First, using the classical methods just quoted, we try to find out the characteristic atomic groups included in the macromolecule. Secondly, we investigate how these groups are arranged, and we describe their whole assembly with different parameters, according to the type of the macromolecule. If the latter is a quite rigid particle (as a small crystal would be, for example), we use the simple concepts of shape and size. If it is not (as would be the case for a linear and flexible chain of a high-polymer molecule), we use some means of statistical description, as we shall see later on. But the important fact is that for this type of macromolecule it is necessary to add to the ordinary structural data a set of new morphological parameters available to new techniques of investigation.

We could perhaps compare a macromolecule to a large building. The short-range methods enable one to know the kind of stones it is composed of, and even to recognize pieces of walls, windows or staircases, but they cannot give us any idea as to the arrangement of all the parts together. They have to be completed by methods giving the general outline of the building the morphology of which is under investigation. From this point of view, we can give a rough estimate of the limits of the macromolecular domain. It begins when the molecule contains a sufficiently large number of atoms, or atomic groups, to require the use of morphological parameters for its complete description. Despite the fact that each case has to be considered in particular, this number in practice lies around one hundred. At the other end of the scale, particles which can be seen under an optical microscope—that is to say, of a size of about 0·2μ—are no longer considered as being macromolecules, since, above that limit, the determination of size and shape implies the use of very straightforward macroscopic methods.

We can conclude, therefore, that when a molecule lies in this range of dimensions (10–10,000 A.), or of molecular weights (about a thousand to several million), it is said to be a macromolecule and its complete description requires: the investigation of its chemical composition, which is a problem of chemistry; the investigation of the detailed structure of the clusters or groups of atoms it is composed of, which is a problem of chemistry or of classical physical chemistry; and thirdly, the determination of morphological parameters connected with its size, shape or statistics of configuration, which is the problem of morphology.

Before starting on this last point, which is my principal aim here, let us consider as an example a macromolecule resulting from the polymerization of a monomer such as $CH_2{=}CH{-}X$ (X not being a hydrogen atom). From mere chemical considerations it can be readily determined that the macromolecule is made up of the assembly of divalent atom groups $-CH_2-\underset{\underset{X}{|}}{CH}-$. Next one wants to know how these atom groups are connected together. Of course, they follow one another, but different types of sequence can be contemplated: first, there is the so-called head-to-head or head-to-tail arrangements; secondly, even in the case of a regular head-to-tail sequence (that is, following Natta, the so-called isotactic polymers) it may happen that all the X atoms can be on the same side of the stretched zigzag chain, or distributed at random on one or the other side; thirdly, it may happen that the law of succession is broken during the process of polymerization and that a branching occurs. These three possibilities—which all correspond to the short-range structure domain—can be investigated by pure chemical means (especially the first and third) or by physical means like infra-red or X-ray spectroscopy.

Finally, if one gives numbers from 1 to N to the N carbon atoms of the backbone of the chain, there remains the problem of the position of atom number i relatively to any other, or to the centre of mass of the whole chain. This is the problem of morphology that we shall now examine.

Let us consider the succession of four atoms C_{i-1}, C_i, C_{i+1}, C_{i+2} (Fig. 1) and choose, as a plane of figure, the plane defined by the two vectors $C_{i-1}C_i$ and C_iC_{i+1}. The position of C_{i+2} is not fixed and can be anywhere on the circle Γ_{i+2}, except a possible effect of steric hindrances, which will be taken into account later on. Thus the backbone of the chain can have an infinite number of possible configurations—from the stretched zigzag line to a more or less inextricable coil—and we shall have to determine the statistics of these configurations. They will depend upon the state of the matter which the chains make up: thus they will be different in the liquid state and in the solid state, and in the latter case they will be different if the piece of matter is, for example, stretched or not. In fact, this correlation is responsible for the special physical properties of high-polymer substances. For the sake of clarity, we shall assume that each

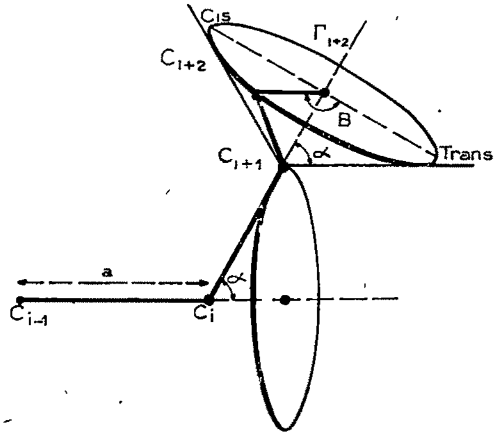

Fig. 1. $a = 1{\cdot}54$ A.; $\alpha = 70°\ 32'$; $\mu = \cos\alpha = \frac{1}{3}$

chain molecule is individualized, or in other words—since the substance cannot be vaporized—that it is placed in a solvent at an infinite dilution. In that case, we shall have to describe for each macromolecule the configurations of an assembly of N points, linked together as already explained.

Up to now, the general approach has been to give the law of probability of position $W_{i,p}(\mathbf{r})d\mathbf{r}$ of any point C_{i+p} in the element of volume $d\mathbf{r}$, $\mathbf{r}$ being the vector $C_i C_{i+p}$. We may consider also the value of $<r_p^2>$, the average of the square of all the possible distances $C_i C_{i+p}$. The interesting point is that often this value can be calculated directly even when it is not possible to know the expression of the function W_{ip}. Then, we can consider $<\rho_p^2>$, the average value for all the configurations, where ρ_p is the distance of C_p to the centre of mass of the molecule. The mean value $\rho^2 = \frac{1}{N} \sum_{p=1}^{N} <\rho_p^2>$ of all the $<\rho_p^2>$ for all the points C_p is another interesting quantity, which is called the radius of gyration of the chain.

In principle, all these parameters can be computed as a function of N, a, and $\mu = \cos\alpha$ (Fig. 1), as soon as we know the elementary law of probability of position of each point C_{i+2} on circle Γ_{i+2}. Unfortunately, this calculation is rather difficult, and it can be completely carried out only under the restriction of assumptions the physical meaning of which is sometimes uncertain. The most simple case is when all the atoms of the assembly are supposed to have no volume and no interactions (such as in an ideal gas). In that case, it can be treated as a Markov process. $<r_p^2>$ can be calculated for all values of p (from 1 to N) as soon as the probability of positions of C_{i+2} on Γ_{i+2} is symmetrical on both sides of the *cis–trans* line (Fig. 1). For very large values of p, it can be calculated in all cases, and one obtains the relationship:

$$<r_p^2> = b^2 p, \qquad (1)$$

where

$$b^2 = a^2 \cdot \frac{1+\mu}{1-\mu} \frac{(1+c)^2+s^2}{1-c^2-s^2} \qquad (2)$$

c and s being respectively the average values of $\cos B$ and $\sin B$.

When equation (1) can be used, then the function $W(\mathbf{r})$ has a Gaussian form:

$$W(\mathbf{r}_p) = \left(\frac{3}{2\pi b^2 p}\right)^{3/2} \exp\left(\frac{-3r^2}{2pb^2}\right)$$

where b^2 is given by equation (2).

When it is assumed that the excluded volume is no longer negligible and that, due to the energy of dilution, there are repulsions or attractions between the elements of the chain, the situation is much more complicated and no probability theory is available. However, with certain assumptions which seem to be supported by experience, an expression can be given for $<r_p^2>$, for $p = N$ only—that is, for the two ends of the chain. It is found that $<r_N^2>$ is proportional to $N^{1+\varepsilon}$, where ε is an increasing function of the second virial coefficient B of the solution. $\varepsilon = 0$ when $B = 0$ (ideal solution).

Finally, in the case of large values of N and for real as well as for ideal solutions, the radius of gyration is given by the equation:

$$\rho^2 = <r_N^2>/(2+\varepsilon)(3+\varepsilon)$$

No matter what the basis of these theoretical or semi-theoretical results may be, the important fact is that the morphological parameters $W(\mathbf{r}_p)$, $<r_p^2>$, ρ_p^2 and ρ^2, which replace the very simple notions of size or shape available for rigid molecules, can be more or less derived from proper measurements performed on solutions.

The general principle upon which these methods are based is to measure the value Φ of a physical character of the solution or its excess compared with the same character of the solvent (that is, viscosity, turbidity, etc. . . .). Generally, Φ is proportional to the number ν of the solute molecules per cubic centimetre, and we may write:

$$\Phi = \nu\varphi = N_0 \frac{c}{M}$$

where N_0 is the Avogadro number, M the molecular weight of the solute, and φ the physical contribution of each single molecule. In general, the magnitude of φ depends on the other molecules in the neighbourhood, so that we may write:

$$\varphi = \frac{N_0}{M}\varphi_0 + c\varphi'_1 + \ldots\ldots$$

where φ_0 is the contribution of a molecule of the solute when it is alone in the whole solution. We have then:

$$\Phi/c = \frac{N_0}{M}(\varphi_0 + \varphi'_1 + \ldots\ldots\ldots)$$

and we can see that the value of φ_0 will be obtained in extrapolating to $c = 0$ the values of Φ/c measured at different concentrations. This is very important, because until now the theories linking φ to the macromolecular data can be set up at their maximum degree of accuracy, when the interactions between solute molecules are negligible. Generally, the interpretation of coefficients φ_1' and so on is more or less unsound—hence the necessity of the extrapolation process just quoted.

We can perhaps try a classification of the main methods into three groups.

(1) Methods which give independently M, or M plus morphological parameters: measurement of the osmotic pressure gives M and also B, the latter being more or less connected with the morphology of the macromolecule; measurement of light scattering also gives M and B, and, moreover, the radius of gyration ρ can be obtained so long as it is larger than a twentieth part—or about—of the wave-length of the incident light.

(2) Methods giving only morphological parameters: measurement of the Brownian translatory diffusion constant.

(3) Methods giving a result dependent simultaneously on the molecular weight and morphology: measurement on intrinsic viscosity; measurement of sedimentation velocity; and measurement of double refraction of flow.

The mass is obtained from osmotic pressure or light-scattering measurements using the general laws of thermodynamics, and this procedure is not open to criticism. The same reliability can be vouchsafed for the theory whereby ρ is derived from light scattering, and it is still fairly sound to derive the value of M from a combination of sedimentation velocity and Brownian diffusion. But all the 'hydrodynamical' methods such as measurement of viscosity, or sedimentation velocity (when used for morphology), have until now had no completely solid theoretical basis. However, they can be used as semi-empirical methods, and viscosity, from this point of view, is quite useful because of its very simple experimental device. In the present state of affairs, there can be little doubt that the light-scattering method is the most reliable, both from the theoretical and experimental points of view. Its generalization to the use of small wave-lengths (for example, X-rays) makes it useful even to the lower limit of the macromolecular domain.

Though it may be felt that the work leading to a complete description of a chain macromolecule—including its morphology—does not need any further justification, it is nevertheless useful to indicate a few aspects of its consequences. Nobody, in fact, doubts the necessity of inquiring about the molecular weight and the short-range structure of a chain, since these factors are of first-rate importance with regard to the properties of matter in bulk—as in rubber or plastic materials—or to the biological specificity of the macromolecule itself in the living organisms, as is the case for proteins or nucleic acids. But it may be reasonable to ask whether it is of any interest to spend so much time and effort in order to describe more accurately the complicated wriggling of a worm-like molecule in its solution.

This question may be answered in a number of ways. First, methods which are widely used for determining molecular weights give—as is the case in the scattering of light—morphological parameters, and the very straightforward curiosity inherent in a scientist's mind would have to be arbitrarily restrained if he were not to try to understand their meaning. Secondly, and more important, the morphological results may lead to significant improvement in the knowledge of the structure itself. Since ρ, for example, depends on steric hindrances, its value depends in principle on the sequence of the atomic groups in a chain. Though it could be slightly changed when head-to-head arrangements are changed to head-to-tail, the effect is much larger when branching occurs. In fact, the determination of morphological parameters is a quite useful way of investigating branching in high polymers.

The third reason appears to me to be the most important one. I have implicitly assumed, in the foregoing discussion, that all the molecules in a solution were identical. Actually, this is not so. A sample of high polymer coming from an autoclave, as well as a sample of nucleic acid extracted from a chromosome, contains a mixture of different molecules. It is then of the utmost importance—for the improvement of our fundamental knowledge in chemistry as well as in biology—to analyse this heterogeneous or poly-disperse medium. The different species have to be characterized and, if needed, separated. This is very often done by using their difference in solubility ; but it can also be achieved by using their difference in morphological parameters (after all, this is the principle of Svedberg's experiments on proteins), and this method is sometimes more direct and can lead to much clearer results. There is little doubt that it will be one of the most efficient means of resolving this problem, which is one of the most irritating in the present state of our knowledge.

As a conclusion, the morphology of large molecules, which is a new and well-defined chapter of physical chemistry, is essential for increasing our knowledge on macromolecules. Of course, this part of science has not the relish of, for example, nuclear physical chemistry. If the first half of this century be thought of as the era of the dawn of nuclear bombs and reactors, perhaps the argument could be advanced, without daring too much, that during the second half the synthesis of materials replacing the traditional natural products and our increased knowledge of fundamental biological processes may in their turn, though in a less spectacular way, weigh very heavily on our future. In this field the morphology of large molecules plays a modest but unquestionable part ; it would be an error to misunderstand it.

CHEMISTRY AND CROP NUTRITION

THE problem of providing adequate food for an increasing world population, and the disastrous and far-reaching consequences of inadequate nutrition, are perhaps more widely realized now than ever before. But it is improbable that it is clearly and universally realized that the ultimate source of our food is the soil and that, were it not for the application of science to agriculture, famine would have overtaken us in Great Britain as a result of an increase in population from ten and a half to forty-nine million during the past hundred and fifty years. This was clearly brought out by Sir William Ogg, director of the Rothamsted Experimental Station, in the ninth Dalton Memorial Lecture, given in Manchester on October 28 under the auspices of the Royal Institute of Chemistry. In the Lecture, which was entitled "Chemistry and Crop Nutrition" and has since been published*, Sir William discussed the contribution of science in general, and of chemistry in particular, to the maintenance of soil fertility.

Early manurial practice, with little or no understanding of its theory, relied in the main upon animal manures, and it was not until early in the nineteenth century that scientific ideas about manuring began to develop as the result of the work of de Saussure, Boussingault, Liebig and others on the Continent of Europe and of Lawes and Gilbert in Britain. The discovery by Lawes in 1842 that treatment of mineral phosphate with sulphuric acid resulted in the production of the phosphatic fertilizer superphosphate, and the setting up of a factory by him for its manufacture, were the beginnings of the modern fertilizer industry.

Lawes and Gilbert during fifty-seven years of active collaboration at Rothamsted carried out investigations into the principles of crop nutrition, the results of which laid the foundations of our present knowledge of manuring. They succeeded in showing the long-term effects of nitrogen, phosphate and potash, both singly and in combination, and some of their field experiments, the classical plots, have been continued at Rothamsted to the present day. Their pioneer work was followed by the use of increasing quantities of nitrogenous, phosphatic and potassic fertilizers in addition to the traditional organic manures. Supplies of phosphatic fertilizers presented no problem since there were known deposits of naturally occurring rock phosphate, and in 1861 the commencement of the working of potash salt deposits ensured a supply of potassic fertilizers. Not until forty to fifty years ago, however, when fixation of atmospheric nitrogen on an industrial scale became possible, could adequate supplies of nitrogenous fertilizers be assured.

---

* Royal Institute of Chemistry. No. 5 Lectures, Reports and Monographs Series of the Royal Institute of Chemistry. Pp 13 (London: Royal Institute of Chemistry, 1955.) 3s.

Sir William directed attention to the recent rapid rise in fertilizer consumption in Britain, the need for fertilizers being accentuated by intensification of cropping and reduction in imports of animal feeding stuffs. A wide range of fertilizers is now provided by modern chemical industry. In addition to ammonium sulphate, superphosphate and basic slag, such nitrogenous and phosphatic fertilizers as liquid ammonia, ammonium nitrate, calcium nitrate, urea, nitrophosphate, triple superphosphate and silicophosphate are available. Supplies of potassic fertilizers are still directly dependent upon deposits of potash salts in various parts of the world. Other major plant nutrients, apart from nitrogen, phosphorus and potassium, include calcium, magnesium and sulphur, and the significance of these was referred to by Sir William; there are also the trace elements (iron, manganese, copper, zinc, boron, molybdenum and chlorine) which, when deficient in the soil, and in some cases when present in excess, are responsible for reduction in crop yield or for disease in both crops and stock.

The precise determination of the manurial requirements of crops is a matter of no little difficulty. Different soils of varying fertility vary in their response to fertilizer application, and that section of the lecture which Sir William devoted to soil testing makes it quite clear that soil fertility cannot be completely explained in chemical terms, since biological, physical and climatic factors are involved also. Total chemical analysis of soil reveals only the quantities of potentially available plant nutrients.

Arbitrary chemical methods for determining the amounts of phosphorus and potassium in the soil that are available to the plant, and the amount of lime necessary to correct soil acidity (the lime requirement), have been developed, and the results, correlated with those of field experiments, can be interpreted in terms of fertilizer application to crops. Nitrogenous manuring, however, still lacks a reliable method of soil analysis upon the results of which guidance can be given, and although field experimentation has provided many useful data, more precision is desirable.

The phenomenon of base exchange in soils and the nature of the clay and humus of soils are of first importance in crop nutrition. Sir William dealt briefly with the researches which have increased our knowledge in this connexion and directed attention to the practical application of the results of these researches. Sound manurial practice involves the maintenance of a suitable balance between the amounts of the various exchangeable cations, and a further application of the principle of base exchange is the use of gypsum in the reclamation of saline and alkali soils in various parts of the world, and of soils flooded by sea water. By the release of exchangeable sodium ions from the soil colloids and their replacement with calcium ions, the deflocculation of the soil colloids is prevented and a favourable soil structure for plant growth ensured. New techniques applied to the study of clay and humus have revealed properties intimately concerned with the physical conditions of soils and with their capacity to take up and retain plant nutrients.

Lastly, Sir William discussed the relationship between organic manures and fertilizers, pointing out that in Britain half the food for crops still comes from farmyard manure, which also improves soil texture and enhances the capacity of the soil to retain water and plant nutrients. Fertilizers, however, are essential since farmyard manure may be deficient in necessary plant nutrients, and moreover, the amounts of organic manures available are not sufficient to meet the needs of present-day intensive farming. The contentions of those who are opposed to the use of fertilizers and who condemn all chemical aids to agriculture on the grounds that there is some vital principle present in organic manures which must be transmitted to the soil if crops, livestock and the human population are to remain healthy, are without scientific foundation. The alleged harmful effects of fertilizers existed before they were discovered and are rife where they have never been used.

This Dalton Lecture was a reminder that, besides his world-famed work in chemistry and atomic theory, John Dalton made notable scientific contributions to meteorology; all agricultural scientists concerned with the water requirements of crops owe to him the first clear ideas of the nature of the evaporation processes, and Dalton may be said to have laid the foundation for modern work in this field.

J. S. Willcox

OBITUARIES

Prof. W. M. H. Greaves, F.R.S.

W. M. H. Greaves, Astronomer Royal for Scotland and professor of astronomy in the University of Edinburgh, who died suddenly on Christmas Eve at the age of fifty-eight, was one of that distinguished series of Cambridge men who have held the Isaac Newton Studentship. His published papers cover a wide range of astronomical subjects, from perturbation-theory to geomagnetism; but his principal interest was the use of photography for the study of the spectra, and especially the continuous spectra, of stars. His appointment as chief assistant at Greenwich, in 1924, gave him his initial opportunity in this field, and he seized and developed it with characteristic enthusiasm. The 30-in. reflector, mounted on the same assembly as the 26-in. refractor (to the great inconvenience of both), was all that was available for such work at the Royal Observatory of that day, but Greaves took such obstacles in his stride. The rather less obvious (but much more formidable) challenge presented by the Greenwich sky was met by rigorous adherence to well-considered rules for observing, and the small probable errors of the results which were obtained testify to the judgment, as well as the courage, which lay behind the whole programme. Six years after his arrival at Greenwich, "gradients" were published for twenty-four stars "suitable for use as spectrophotometric standards", and these intercomparisons were of such quality that they scarcely had to be modified at all as a result of the main programme which followed. This comprised 250 stars, most of them fainter than the standard ones; but the foundations had now been laid, and the advent of the new 36-in. Yapp reflector in 1934 also speeded the work. By 1938, when Greaves was appointed to Edinburgh, there was little still to do except publish the extensive results.

An essential part of photographic spectrophotometry is the calibration of the plates, and since it would have been very time-consuming to use, in this, the long exposures which had to be used on stars, the question of 'reciprocity failure' had had to be faced. Greaves reduced this somewhat venerable bogey to very manageable proportions, and definitely established the value of photography as a precise quantitative tool, at a time when photocells were still too insensitive to compete in this field.

The Second World War came soon after his move to Edinburgh, and for a while his principal concern was with the time service, where he co-operated closely with the Greenwich station that had been evacuated to Abinger; a substantial share of the advance in accuracy which occurred about this time, in spite of difficult conditions, was due to him. After the War, he obtained for his Observatory a badly needed increase in staff, and spectrophotometric data both on the Sun and on early-type stars have come increasingly from Edinburgh in recent years. Extensive work is in progress that would undoubtedly have benefited further from his leadership if he had lived.

Greaves definitely enjoyed taking charge of things, and could keep a committee firmly to the point. He served for six years as secretary of the Royal Astronomical Society, and was president during 1947–49. He was an active member of several commissions of the International Astronomical Union, serving for seven years as president of the one for photometry. His influence in the British National Committee for Astronomy was considerable, and he was one of the keenest sponsors of the plan for a large paraboloid at Jodrell Bank.

He will be warmly remembered by those who have worked under him, and with him. His complete integrity, and his devotion to astronomy, were unquestionable; but his numerous generosities may often have been less commonly known. The proportion of his papers which bear also the names of one or more subordinates is high, and this reflects not only his scrupulous fairness but also his power of stimulating the best efforts of his staff in the first place. He was capable of brusqueness, and even more, on occasion; but those who could see past this will remember the very real tact and skill with which he would guide and help all, whether old subordinates or new colleagues, who were associated with him.

R. d'E. Atkinson

Dr. F. H. Burstall

Dr. F. H. Burstall, who died on December 2 at the untimely age of fifty-two, had spent the whole of his working life at Teddington. He was one of a small band who were recruited by the late Sir Gilbert Morgan to staff the Chemical Research Laboratory (of the Department of Scientific and Industrial Research) when it was founded in 1925; and it can be said with truth that no one has done more to establish the prestige and repute that the Laboratory has, in the meantime, achieved.

The second son of the late Prof. F. W. Burstall (who held the chair of mechanical engineering and was dean of the Faculty of Science in the University of Birmingham), Francis Burstall did not follow the profession in which other members of his family have achieved distinction. After graduating at Birmingham with first-class honours in chemistry, he became research assistant to Morgan, who had been his professor and was about to take up a new appointment as superintendent of the Teddington Laboratory.

As a young man Burstall was entirely unsparing of the time and effort he applied to chemical research. He made substantial contributions to the organic chemistry of selenium and tellurium, undeterred by the frequently obnoxious nature of the materials he had to handle. It was, however, by his work on metallic co-ordination compounds that he won recognition as an authority in a field then little cultivated. In a book published in 1933, of which he was co-author with Morgan, he provided an admirable survey of the more recent developments in this branch of inorganic chemistry.

When war came in 1939, Burstall was obliged to take on a succession of problems which, important though they were at the time, offered little of continuing interest, and it was only with the ending of hostilities that his Department was able to make the best use of his very versatile ability. In 1947 he was placed in charge of a small section set up to study the analysis of uranium and thorium ores on behalf of the Department of Atomic Energy. The extraordinary value of the contribution that he and the staff he led (and inspired with some of his own enthusiasm) were able to make to the national effort in this new field was quickly recognized. Greater responsibilities were laid upon Burstall, and his unit ultimately became so large that an extensive new building was constructed and equipped to accommodate what now became the Radiochemical Group of the Chemical Research Laboratory. Those who knew what Burstall put into his task will always see in this fine laboratory a memorial to his success in what, unfortunately, was to be the last phase of his scientific career. Much must remain untold; nevertheless, the series of papers in which he and his colleagues revealed their application of chromatography to the separation of metals indicate the power and generality of a technique they were among the first to use. The formal seal was set on Burstall's accomplishments in chemical research when in 1952 he attained the academic distinction of D.Sc. of the University of London.

Modest and self-effacing, Burstall was nevertheless a man whose judgments were shrewd, being based on wide (if unparaded) knowledge and deep self-communion. He had an extraordinary charm for his friends and colleagues. This was due to the utter impossibility for him to do or say anything in the slightest degree unkind or inconsiderate. His main preoccupation throughout his life was with chemistry, which to him was far more than the means to a livelihood. To purely personal advancement he never gave a thought; nevertheless, he found a high degree of self-fulfilment as a scientist in the service to which he gave his loyalty and whose traditions he upheld.

In the course of his last illness he underwent two major operations and it almost seemed after the first that hope could be entertained of a recovery. Unfortunately this was not to be. Dr. Burstall bore his grievous afflictions with stoicism for more than twelve months. He is survived by his wife, whom he married in 1929, and two sons.

E. A. COULSON

Prof. G. T. R. Hill

PROF. G. T. R. HILL, who died recently at his home in Ireland, was a member of a very distinguished family. His father, the late Dr. M. J. M. Hill, was professor of mathematics and a vice-chancellor of the University of London. His elder brother, the late Air Chief Marshal Sir Roderic Hill, became rector of the Imperial College of Science and Technology and also vice-chancellor of the University of London, and his sister, Dr. Gwen Hilton, is now director of the Radiotherapy Department of University College Hospital.

The two brothers both had close interests in aeronautical engineering, and though their careers were quite different, one was very much complementary to the other in its contribution in this sphere to progress during the past thirty years.

Even as a boy, Geoffrey Hill's future career was unmistakably marked out. He spent much of his spare time making aircraft models, and at the age of seventeen secured a place for one of them at the Children's Exhibition at Olympia. He was educated at University College School and afterwards at University College, London, where as an engineering student he graduated in 1914. After a period of active service in the Royal Flying Corps at the beginning of the First World War, when he rose to the rank of captain and was awarded the Military Cross, he undertook responsibilities in aeronautical research for the Air Ministry. After demobilization in 1919 he pursued his absorbing interest in aeronautics as an experimental engineer and chief test pilot to Messrs. Handley Page, Ltd. By this time he had acquired a background of knowledge and experience which, coupled with his inventive ability, enabled him, in collaboration with his brother, to conceive the idea of the tail-less aircraft or Pterodactyl as it was afterwards called.

In 1922 Hill was awarded an 1851 Exhibition Senior Studentship and after two years of research to test the validity of the principles that the two brothers had enunciated, he began the design and construction of a Pterodactyl. The work was supported in its early stages by the Aeronautical Research Committee and eventually the machine was further developed in association with the Westland Aircraft Co. when he joined that firm in 1926. It was shown to the public for the first time at the R.A.F. pageant at Hendon and is now in the Science Museum at South Kensington, where it bears witness to the great contribution which the two brothers made to aeronautical science by establishing the important principles demonstrated in this machine. The industry to-day owes them a deep debt of gratitude.

In 1934 Geoffrey Hill returned to his old College as Kennedy professor of engineering, and he held that post with great distinction until 1947, when he resigned to re-enter the aircraft industry as consultant to Short Brothers and Harland, Ltd., of Belfast. During the Second World War he was seconded to the Air Ministry and later the Ministry of Aircraft Production for research work, and as a pioneer in the invention of the isoclinic wing he made valuable contributions in helping to maintain the superiority of the Allies in the air. He was elected to fellowship of the Royal Aeronautical Society, and was awarded the D.Sc. in engineering of the University of London.

His most delightful personality and his charm of manner will always be treasured by the wide circle of his friends and acquaintances. His death at the early age of sixty is a great loss, not only as a personal one, but also to the science of aeronautical engineering.

H. M. BARLOW

NEWS and VIEWS

Wellcome Museum of Medical Science : Lieut.-Colonel C. A. Bozman, O.B.E.

LIEUT.-COLONEL C. A. BOZMAN has been appointed director of the Wellcome Museum of Medical Science, and will take up his duties on February 1. Colonel Bozman, who received his medical training at the University of Edinburgh, joined the Indian Medical Service in 1924. He held various public health and laboratory appointments, including that of director of public health, Burma, and became a public health commissioner to the Government of India. After his retirement in 1947 he was successively lecturer in public health in the University of St. Andrews, health counsellor at the British Middle East Office, Cairo, and professor of preventive medicine at the University College of East Africa (Makerere College). His new post with the Wellcome Foundation will enable Colonel Bozman to apply his wide knowledge of tropical medicine and pathology in the service of a Museum which has specialized in this field.

Glasshouse Crops Research Institute : Dr. W. F. Bewley, C.B.E.

DR. WILLIAM F. BEWLEY retires from the post of director of the Glasshouse Crops Research Institute next summer. Bewley was educated at the University of Durham and first joined the staff of Rothamsted Experimental Station, being seconded for service in the Royal Field Artillery during the First World War. While at Rothamsted he collaborated with the late Dr. H. B. Hutchinson on the classic researches on partial sterilization of soil which were later to prove the salvation of the tomato industry. In 1919 he went to the research station in the Lea Valley founded in 1914 by the glasshouse growers of the district and later to become world-famous under his leadership as the Cheshunt Experimental and Research Station. He became director in 1921, and instituted the long series of experiments on glasshouse crops which laid the foundations of modern techniques. His many years of experience, first as a mycologist and later as an authority on all aspects of glasshouse cultivation, were summed up in his two standard books, "The Diseases of Glasshouse Crops" and "Commercial Glasshouse Crops". In 1954, the old Cheshunt Station became the new Glasshouse Crops Research Institute, with Bewley as director, and in 1955 its staff moved to the new site at Toddington near Littlehampton. Bewley's warm, friendly nature, together with his exceptional powers of lucid exposition, have long endeared him to the industry, and to-day there is no man who stands higher in the respect and affection of the glasshouse growers of Great Britain. Not least among his admirers are the growers of the Channel Islands, to whom he pays regular visits.

Mr. F. W. Toovey, O.B.E.

MR. F. W. TOOVEY, who has been appointed to succeed Dr. Bewley, graduated from the Imperial College of Science and Technology, London, where he was awarded the Forbes Medal and Prize. He was then selected for the Colonial Agricultural Service. and after postgraduate work at Cambridge and in Trinidad, was appointed to the Nigerian Agricultural Department in 1935. In Nigeria his work was concerned almost exclusively with the oil palm, a crop of the greatest importance in the economy of the country. Twenty years ago, very little study had been devoted to the crop, but a lead had been given by the fine work that was being done by the Belgians at the I.N.E.A.C. In 1938 Mr. Toovey was sent to the Belgian Congo to report on the progress made in oil palm-research there, and returned to take part in the development of the Oil Palm Research Station of the Agricultural Department of Nigeria. Largely under his direction, this station, which covered, initially, 4,000 acres of undeveloped tropical forest, was built up as the main centre for oil palm research in Nigeria, with many supporting out-stations. In 1952 the station assumed responsibility for research in all the British West African territories, becoming an autonomous institute known as the West African Institute for Oil Palm Research (W.A.I.F.O.R.). Mr. Toovey was appointed its first director, and for his services was made O.B.E. in the New Year's Honours list of 1955.

Chair of Marine Engineering at Newcastle upon Tyne

THE Council of King's College, Newcastle upon Tyne (University of Durham), has announced the receipt of £35,500 from local industrial firms towards the endowment of a new chair of marine engineering at the College. This sum is additional to some £22,000 which was contributed to the College two years ago and earmarked for the development of marine engineering studies. The two sums together provide sufficient funds to proceed immediately to the appointment of the first professor. A separate undergraduate course in marine engineering has been provided at the College—then Armstrong College—since 1913, in the Department of Mechanical and Marine Engineering, of which the present head is Dr. Aubrey Burstall, professor of mechanical engineering. In August 1954 he suggested to the Council that the Department had grown so large that a second professor should be appointed to work in his Department and that he should be designated professor of marine engineering. This proposal was accepted and afterwards widely approved by industrialists and others concerned in marine engineering in Britain. It is hoped to attract more university men into the marine engineering industry and to develop a centre for marine engineering studies at King's College, where there already exists one of the largest university departments of naval architecture (under Prof. L. C. Burrill) in Britain.

Protection against Ionizing Radiations

THE International Labour Office made history in the field of protection against ionizing radiation when, in 1949, it introduced its Model Code of Safety Regulations. The relevant sections of the code are included in a report submitted to the International Conference on the Peaceful Uses of Atomic Energy, Geneva, 1955 (The Protection of Workers against Ionising Radiations (International Labour Office, Geneva, 1955). 50 cents ; 3*s*.). In 1955 it seems, as the report states, "out of date in some respects . . . and is now due for revision". Nevertheless, this code of practice has been in print and outdated, while no British National Code has yet appeared since the demise of the British X-ray and Radium Commission. A report, therefore, by the International Labour Office, progressive as it is in this field, is worthy of study. It recommends the adoption of the general principles of protection laid down periodically by the International Commission on Radiation Protection. If it accepts its own recommendation, it will have to revise its Model Code drastically in a number of important respects—including incidentally Regulation 208.7, which states that photographic dark rooms should have some natural lighting. It reviews the effect of ionizing radiations on human beings (in parts this is a little naive, indicating that the author was not a medical man) ; the uses of ionizing radiations ; protective measures ; problems arising in uranium mining and processing ; and safety in transport of radioactive materials. It is at its best when it deals with the problems met with to-day in industry. It therefore behoves the industrialist about to use the newly available tools of radioactivity and ionizing radiation to study it. The industrial medical officer and the Ministry of Labour will note, no doubt, the recommendation of the International Labour Office that diseases due to ionizing radiations be included in the international list of occupational diseases to be notified to the labour inspectorate.

Veterinary Research in Britain

IN the committee stage of the Agricultural Research Bill, which received its third reading in the House of Commons on January 26, Mr. A. J. Champion, Captain J. A. L. Duncan and Mr. Leslie Hale pressed for more attention to veterinary research and to livestock farming as contrasted with crop husbandry. For the Government, the Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, Mr. C. R. H. Nugent, while maintaining the view previously expressed that a separate veterinary research council is undesirable and that veterinary research as well as general agricultural research appropriately come under the Agricultural Research Council, promised to take note of the comments made and particularly of the importance of developing preventive veterinary work in agriculture to-day. He pointed out that the Lord President's Committee would consist of the Minister of Agriculture, Fisheries and Food and the Secretary of State for Scotland.

The Houghton Poultry Research Station

THE Animal Health Trust founded its Poultry Research Station at Houghton, Huntingdonshire, some seven years ago, and under the leadership of Dr. R. F. Gordon the staff has done much useful work on behalf of the poultry industry. The Trust and the Agricultural Research Council have now agreed on financial co-operation on lines which should satisfy the aims of both the Trust and the Council for the expansion of research facilities and meet the conditions essential to the provision of government financial support. Under these arrangements the Trust will contribute one-third of the net annual maintenance expenditure up to £10,000 a year and the Agricultural Research Council will contribute the other two-thirds, with freedom to each party to give more if they wish and if it is in the interests of the Station. The Station is to have an independent status and will be known as Houghton Poultry Research Station. It will be governed by a board of nine members who have been appointed by the Lord President of the Council, the Minister of Agriculture, Fisheries and Food and the Secretary of State for Scotland, three of them having been nominated by the Animal Health Trust. They are as follow: Mr. T. H. Turney (chairman), Prof. E. C. Amoroso, Mr. H. Finn, Mr. G. Guttridge, Mr. F. Grove, Prof. K. Mather, Lord Stamp, Prof. E. G. White and Dr. W. R. Wooldridge.

New Zealand Heavy-Water Scheme

THE United Kingdom Atomic Energy Authority, after consultation with the New Zealand Government, has decided to withdraw from participation in the Wairakei Scheme. This scheme provided for utilizing geothermal steam for the generation of electric power and for the manufacture of heavy water, the New Zealand Government being interested in the former product and the Atomic Energy Authority in the latter. It has now been found that the cost of constructing the heavy-water plant would be much higher than was originally estimated. A company, Geothermal Development, Ltd., was formed for this purpose, and this will be wound up in due course. The New Zealand Government is to continue with the power station project.

Combustion Institute

THE great interest in research in the field of combustion in the post-war period has been made evident by the support accorded the three symposia held in 1948, 1952 and 1954. To undertake the responsibility of organizing such symposia, a sub-committee was formed in the United States, with representatives from industry, government and universities, and this sub-committee, in conjunction with the honorary members of the Standing Committee in Belgium, France, Great Britain and Netherlands, recommended that a "Combustion Institute" should be founded. The Institute was incorporated in the State of Delaware on July 1, 1954, and at the first meeting of its members, held in Pittsburgh on September 1, 1954, during the fifth symposium, a board of directors of fifteen members was elected, and two working committees were established—the Executive Committee and the Combustion Institute Committee. The latter comprises representatives from a number of different countries, and it is intended that the symposia should continue to be international in character. It is in no way the intention of the Combustion Institute to compete with other societies either in its meetings or publications, but its main object is to encourage activity in this important field crossing the boundaries of so many scientific and engineering disciplines. The first symposium under the auspices of the newly formed Institute will be held at Yale University during August 19–24. The British members of the Combustion Institute Committee (Sir Alfred Egerton, Dr. J. S. Clarke and Mr. P. Lloyd), with Dr. J. W. Linnett, form the British Committee. Further information can be obtained from the assistant secretary, Miss H. Smith, c/o Joseph Lucas, Ltd., Great King Street, Birmingham 19.

Geochemical Society

AT a meeting of the Geological Society of America, held in New Orleans on November 7, the organization of a new society, the Geochemical Society, was completed, and a constitution was adopted which specifies that "The object of the Society shall be to encourage the application of chemistry to the solution of geological and cosmological problems" and that "any person who is qualified to advance the objects of the Society shall be eligible for membership". Thus membership is open to physicists, biologists, mathematicians, oceanographers, meteorologists, etc., as well as chemists and geologists. Those wishing to become charter members should send their names, addresses, fields of interest, and a year's subscription (2 dollars) to the treasurer, Dr. George T. Faust, U.S. Geological Survey, Washington 25, D.C. Names of those who might be interested, but who are not on the "List of Persons doing Research of Interest to Geochemists" (*Geochimica et Cosmochimica Acta*, 6, 132; 1954) would also be appreciated. The following have been elected officers of the Society: *President*, Earl Ingerson (U.S. Geological Survey, Washington); *Vice-President*, Julian R. Goldsmith (University of Chicago); *Secretary*, John C. Maxwell (Princeton University); *Treasurer*, George T. Faust; *Councillors-at-Large*, J. W. Greig, W. F. Libby, W. T. Pecora, W. W. Rubey, G. R. Tilton and H. S. Yoder.

The Hakluyt Society

THE Hakluyt Society exists to publish original narratives of important voyages and travels and other geographical records. The volumes, two of which are generally issued for each year, are made up of the original documents together with introductory material of great value to the geographer, historian, ethnologist and, not infrequently, to other students of the natural sciences. Since its beginning in 1846, the Society has issued one hundred volumes in its first series and one hundred and seven in its second (current) series. Throughout the greater part of its history, its annual subscription remained unchanged at one guinea, and only in 1955 was it increased to two guineas, a modest sum to pay for two volumes of its publications. At irregular intervals the Society produces an 'extra' series. The great collections of Richard Hakluyt and Samuel Purchas have already appeared in this series, these being little more than reprints of the original works. Perhaps the most ambitious and the most important work in this series is the definitive publication of the "Journals" of Captain James Cook, edited by Dr. J. C. Beaglehole. Here the Society is not merely following its normal practice in printing journals and other documents that have not previously been published from the original manuscripts, but is adding a volume dealing particularly with the scientific results of these great voyages. Vol. 1, covering the first voyage, and a portfolio of original charts and views drawn on all three voyages, have recently been published; the whole project will be completed in four volumes. Last year Mr. J. N. L. Baker succeeded Mr. Malcolm Letts as president

Mr. Letts has occupied the office for five years and has made valuable contributions to the publications of the Society. The honorary secretary of the Society is Mr. R. A. Skelton, superintendent of the Map Room of the British Museum (London, W.C.1), who has done much in helping with the publication of the Cook volumes.

Physics and Philosophy

THE first Robert Grosseteste Memorial Lecture, given by Lord Cherwell on May 21 last, was delivered most appropriately in the Chapter House of Lincoln Cathedral; it has now been published (pp. 21. London: Oxford University Press, 1955; 2*s*. 6*d*. net). In it Lord Cherwell performs a valuable service in pleading for a closer understanding between physics and philosophy such as, in broad outline, existed in the lifetime of the great bishop and scholar in whose honour he was speaking. An exceptionally clear picture is presented of the æsthetic choice before the investigator in modern physics, coupled with the recognition that an axiological element is not excluded, thus revealing a measure of personal preference. It is one of the major tragedies of modern thought that the natural philosopher of to-day is expected to know all the answers, whereas, in fact, he is taking a quite limited sector of awareness as his plane of discourse—and likewise for workers in other fields of knowledge. The well-known antipathy of metaphysicians towards mathematics, and the reluctance of physicists to meditate upon fundamentals, are symptoms of a somewhat arid intellectual climate in which the triumphs of science have been won, but which is not necessarily conducive to "helping bewildered humanity to confront the mysteries of existence".

Green Earthworms

THE eastern United States has been invaded by a plague of green earthworms (Smithsonian Institution News Release, Dec. 9, 1955). In a few areas these immigrants from China and Manchuria have become a serious problem for keepers of golf courses because of their borings in putting greens. In a night they may cover a best-kept green with little piles of earth. This particular earthworm, *Pheretima hupeiensis*, was first described more than fifty years ago from the Hupei Province of China, and its first appearance in the United States, near Philadelphia, was noted in 1933. Since then there have been numerous reports from golf clubs which almost unquestionably deal with the same species. Presumably it was introduced into America on some kind of nursery stock from China and has been spread by transportation of turfs from one golf course to another. It is such a serious problem in Westchester County, N.Y., and southern Connecticut that the Connecticut Agricultural Experiment Station has instituted a control programme. It is a slender worm, 1–3 in. long. Its colour varies from pale green to deep olive. A distinct purple or black line is apparent on the back.

The Cross-Bill

ONE of the excellent leaflets issued by the Forestry Commission deals with the cross-bill, *Loxia curvirostra* (Leaflet No. 36; pp. 11. London: H.M.S.O., 1955; 9*d*. net). Besides an illustrated description of the bird, accounts are given of its habitat, song, behaviour, feeding habits and distribution in Great Britain. For the forester the important section is one describing its economic significance. Although the cross-bill does not breed anywhere in Great Britain in numbers large enough to cause the slightest alarm to foresters, it cannot be described as a 'beneficial' bird; it takes some insects and some of them may be harmful to sylviculture, though the amount involved is too small to be of economic account. The leaflet recommends that, for the present, it is best to regard the cross-bill as a highly specialized inhabitant of mature coniferous woodland the ordinary life-history and feeding habits of which are by no means well known, and which—in respect of the periodic invasions—poses a problem of great biological interest still awaiting solution.

Gold Coast Pteridophyta

A COMPREHENSIVE list of the Pteridophyta in the Gold Coast has recently been prepared by C. D. Adams and A. H. G. Alston (*Bull. Brit. Mus.* (*Nat. Hist.*) *Bot.*, 1, 6, 143; 1955). This is an up-to-date statement of the taxonomy, nomenclature and broad distribution of most of the indigenous species, and includes habitat notes based on extensive field observations in the Gold Coast and neighbouring territories and on collectors' annotations. The classification used for the ferns is that of R. E. Holttum (1947). The Pteridophyta are poorly represented in the savannah country and include only such plants as show a geophytic habit or are aquatic annuals. Endemic species are stated as being almost totally absent. Pteridophytes other than the ferns are represented by a relatively small number of species.

Films in Human Relations

THE industrial committee of the Scientific Film Association organized a conference at Ashorne Hill during May 24–26, 1955, on the use of the film in the improvement of human relations in industry, and the report of the proceedings (pp. 24; from the Association; 2*s*. 6*d*.) shows the need for more readily accessible information about available films that are suitable for education and training in industry. A new and comprehensive catalogue of all industrial films available in Great Britain is both desirable and necessary. Such a publication would not be an end in itself. To be of lasting use it would have to be supplemented by an information service which could keep catalogued information up to date and answer specific inquiries about industrial films. The Scientific Film Association is anxious to provide such a service, which can, however, only be established when sufficient funds are available. To gather information in this way is an important step which must be taken before further serious investigation can be made into the use and efficacy of films in industry.

Indian Society of Genetics and Plant Breeding

THE sixteenth annual general meeting of the Indian Society of Genetics and Plant Breeding was held at New Delhi on December 12 under the presidentship of Dr. T. R. Mehta, joint director of research, Madhya Bharat College of Agriculture and Research Institute, Gwalior, who delivered an address on "The Genotype in Agriculture". At the meeting it was decided to organize a symposium, to be held later in the year, on the role of genetics in the improvement of tropical crop plants. The following were elected officers of the Society for 1956: *President*, Prof. V. M. Chavan (Poona); *Vice-Presidents*, Dr. P. N. Bhaduri (New Delhi) and Dr. G. S. Murty (New

Delhi); *Secretary*, Dr. M. S. Swâminathan (New Delhi); *Treasurer*, Dr. N. L. Dhawan (c/o Division of Botany, Indian Agricultural Research Institute, New Delhi-12); *Editor*, Dr. B. P. Pal (New Delhi); *Councillors*, Shri P. D. Gadkari (Indore), Dr. B. S. Kadam (Rajkot), Dr. N. Parthasarathy (Cuttack), Dr. Pushkarnath (Simla), Dr. R. H. Richharia (Sabour) and Dr. T. S. Venkataraman (Madras).

University of Birmingham

The Huxley Lecture for 1956 of the University of Birmingham will be delivered by Dr. Harry Godwin (reader in Quaternary research, University of Cambridge) on February 23, at 5 p.m., his subject being "The Quaternary History of the British Flora". The Sir Josiah Mason Lectures of the University, which have already started, will be continued by Prof. Max Gluckman (professor of social anthropology in the University of Manchester) on successive Thursdays at 5.15 p.m. until March 8, his subject being "Conflict and Cohesion in Zululand". The following have been appointed Research Fellows in chemistry: J. A. Gascoigne and Miss M. Ramsay (British Rayon Research Association Fellows), Dr. H. Weiss, of the Technische Hochschule, Vienna (British Council Research Fellow), and Nadim A. Ghanem, of Alexandria.

Admiralty Student-Apprenticeship Scheme

The Admiralty has decided to supplement its craft-apprentice scheme by the recruitment of student apprentices who will be selected and trained specifically to meet the Admiralty's requirements of draughtsmen and subordinate technical officers. Student apprentices will be given five years of training in one of the four main dockyards (Chatham, Devonport, Portsmouth and Rosyth), at which basic knowledge of the building and repair of ships will be imparted, and this will be followed by detailed training in the work of one particular branch—naval construction, marine engineering or electrical engineering. Two days a week theoretical instruction will be given in the technical colleges in the Royal Dockyards. A few of the students will be selected for advanced training with the view of their entry into the Royal Corps of Naval Constructors or training as electrical engineers. The Admiralty will continue its long-established craft-apprentice scheme for boys of 15–17 years, and on the basis of their progress during the first year such craft apprentices will be eligible for transfer to the direct-entry student scheme. Student apprentices will be recruited by an open competition conducted annually by the Civil Service Commission; candidates must be 16–18 years of age and will take a written examination in mathematics, physics and chemistry, and English, followed by an interview. The first examination will be held in April, and further information can be obtained from the Secretary, Civil Service Commission, Burlington Gardens, London, W.1.

Announcements

Dr. John Lamb and Dr. J. H. Westcott, lecturers in the Imperial College of Science and Technology, London, have been appointed to University readerships in electrical engineering tenable at that College. The title of reader in anatomy in the University of London has been conferred on D. H. L. Evans and D. A. Sholl in respect of their posts at University College, London.

The following appointments have been made in the Development and Research Department of the Mond Nickel Co., Ltd.: G. L. Harrison, to succeed A. D. Busby as a development metallurgist in London, where he will work in the field of cast iron; P. D. Wilmot, to be a development chemist in London, where he will be concerned with the chemical and chemico-physical aspects; and J. H. Gittus, to be section leader of the Cast Iron Section at Birmingham.

The Council of the Royal Society has awarded a Mackinnon Research Studentship to Dr. C. J. Waddington, of the H. H. Wills Physical Laboratory, University of Bristol, for his work on the nature and properties of the primary cosmic radiation.

The British Museum (Natural History) has received from the Malacca Museums Board a skull of a beaked whale, *Mesoplodon stejnegeri*. This specimen is the first of its kind to be acquired by the Museum, and the species is represented in only one other museum in the world (the United States National Museum, Washington).

The journal *Vox Sanguinis* is no longer being published by the Central Laboratory of the Netherlands Red Cross Blood Transfusion Service. Publication is now in the hands of the company S. Karger, at Arnold Bocklin-Strasse 25, Basle, to which all inquiries should be sent.

A symposium on vegetable tannins, organized by the Society of Leather Trades' Chemists, will be held in the Chemistry School, Cambridge, during April 12–13 under the chairmanship of Prof. R. D. Haworth and Dr. F. E. King, respectively. Thirteen papers have so far been arranged, including three from workers in Heidelberg; but other papers will be considered if sent in without delay. Registration forms for the symposium and further information can be obtained from the honorary secretary, G. H. W. Humphreys, c/o Forestal Central Laboratories, Harpenden, Herts.

The third Easter symposium in agricultural science of the University of Nottingham will be held at the School of Agriculture, Sutton Bonington, during April 23–25. The main theme will be the growth of leaves, and the four sessions will deal, respectively, with general aspects of growth and development, initiation and growth of leaf primordia, the expansion of leaves, and the influence of external factors on leaf growth. Further information can be obtained from Prof. F. L. Milthorpe, School of Agriculture, University of Nottingham, Sutton Bonington, Loughborough.

The Medical Research Council is offering a number of fellowships for the academic year 1956–57, as follows: Rockefeller, Eli Lilly and Lederle travelling fellowships in medicine (2,700 dollars a year or 3,900 dollars for married men), for graduates resident in Great Britain with previous research experience in clinical medicine or surgery, or in some other branch of medical science, to work at a centre in the United States or elsewhere abroad, before taking up positions for higher teaching or research in Britain; Dorothy Temple Cross research fellowships in tuberculosis (£650 a year or £900 for married men), for British subjects to devote themselves to the advancement of knowledge of tuberculosis at a centre outside Great Britain. Application forms (to be returned by March 15) and further particulars can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

CENTENARY OF THE GEOLOGICAL SURVEY IN SCOTLAND

On January 16 Dr. W. J. Pugh, director of the Geological Survey of Great Britain, and Dr. A. G. MacGregor, assistant director in Scotland, welcomed a distinguished company at a ceremony and exhibition of work, in the Edinburgh office of the Geological Survey, marking the completion of an extension of that office and of a hundred years of Geological Survey work in Scotland. Among the guests were Mr. D. L. Macintyre and Mr. J. MacMinn, of the Ministry of Works, who were responsible for the building operations; Sir Walter Drummond, chairman of the Geological Survey Board, Sir Edward Bailey and Dr. W. F. P. McLintock, former directors of the Survey; Dr. Murray Macgregor and Mr. T. H. Whitehead, former assistant directors in Scotland; professors of geology from the Scottish universities and representatives of Scottish learned societies, professional institutions and government departments, etc., with special geological connexions. The older generations of Scottish Survey geologists were represented by descendants of Dr. B. N. Peach, Prof. James Geikie, Dr. John Horne, Dr. C. T. Clough and Sir John Flett.

Geological Survey work in Scotland commenced in a small way in 1854, at the time when Scottish six-inch-to-mile Ordnance Survey topographical maps began to appear. The first worker, Sir Andrew Ramsay, mapped in Scotland for only a few months. In 1855 his work was continued in the Lothians area, Berwickshire and Fife by H. H. Howell (coalfield areas) and by Sir Archibald Geikie.

Work in Scotland has been successively under the direction of Sir Andrew Ramsay (1854–67), Sir Archibald Geikie (1867–82), H. H. Howell (1882–99), Dr. John Horne (1899–1911), Sir John Flett (1911–20), Dr. Walcot Gibson (1920–25), Dr. Murray Macgregor (1925–45) and T. H. Whitehead (1945–52).

The economic importance of six-inch-to-mile regional geological mapping was early in evidence, for in 1858 Geikie was able to indicate to James Young, founder of the Scottish oil industry, the general distribution of West Lothian oil-shales. The first one-inch-to-mile geological map (Edinburgh Sheet) was published (hand-coloured) in 1859 and the first memoir (Edinburgh District) in 1861. The first six-inch coalfield maps were also published in that year. One-inch maps were coloured by hand up to 1910, when the Edinburgh sheet was one of the first to be colour-printed. The Scottish coalfields were largely covered by 1880. By 1890 the whole of Lowland Scotland, East Highland coastal districts as far north as Dornoch, and part of the North-west Highlands had been published on the one-inch scale.

It was in 1883 that Geikie, in his second year as director general, brought the North-west Highlands under survey. His object was to test conflicting current hypotheses regarding the sequence and structure of the older Highland rocks by carrying out detailed regional mapping in the only area where fossils were known to occur in some of the rocks concerned. The brilliant work of B. N. Peach, J. Horne and their colleagues at once made the region internationally famous for its complex, but clearly demonstrable, tectonic structure. A summary of results was given to the Geological Society of London in 1888, and a monumental official memoir on the region was published in 1907.

Scottish work during 1882–1901 was almost entirely in the Highlands. From that time until to-day, except during the two World Wars, primary Highland survey and revision of coalfield areas have gone on concurrently. The wide knowledge, enthusiastic leadership and literary ability of Dr. John Horne, assistant director during 1901–11, led to a good output of Highland and Lowland maps and memoirs during that period. Sir John Flett's remarkable Scottish petrographic output while petrographer during 1901–11, and his delegation of some petrographic research to others, were of great assistance to Horne. Flett's initiative and drive while assistant director in Scotland (1911–20) and director in London (1920–35) ensured that good progress with the publication of Highland and Lowland maps and memoirs was maintained. The first revision of the main Scottish coalfields and of the West Lothian oil-shale area was complete before 1939; recent economic work has included a second revision of the Lothians coalfield.

During the first three decades of the twentieth century scientific discoveries of fundamental importance to volcanology were among the results of the Survey's Highland work. A. Harker in Skye and Rhum, C. T. Clough, H. B. Maufe and E. B. Bailey in Appin and Lochaber, Clough, Bailey, E. M. Anderson and others in Mull, and J. E. Richey in Ardnamurchan vastly supplemented previous knowledge of Scottish Tertiary and Devonian volcanoes and of volcanic mechanisms in general. Bailey and Maufe also revolutionized ideas on the tectonic structure of the schists of the South-west Highlands.

Pioneer British geophysical work with the Eötvös gravity balance was organized by Sir John Flett and carried out in Scotland by W. F. P. McLintock and J. Phemister between the years 1927 and 1931.

During the First and Second World Wars all available staff were employed on work of economic importance. One result of this activity was the gathering together, for the first time, of a great amount of information on Scottish mineral resources, additional to coal and oil-shale. Much of this geological and mining information has been made generally available by publication. The Survey's geological advice led to the exploitation of virgin deposits of bauxitic clay in Ayrshire, of iron-ore in Raasay, of silica sand in Morvern, of mica in Knoydart and elsewhere, and of potash feldspar in South Harris. These raw materials made notable contributions to the war-time economies of Britain, and in two instances still command a market.

The First World War saw the initiation of a long series of memoirs on the economic geology of the Scottish coalfields. Dr. Murray Macgregor, who was prominent in this undertaking, has done more than anyone else to convince Scottish coalmasters and National Coal Board officials of the practical importance of Geological Survey methods and work. For some thirty years, during twenty of which he was assistant director (1925–45), he encouraged and influenced the constantly expanding economic work of the Scottish Survey.

During the hundred years of Survey work in Scotland, seventy-two memoirs on general and scientific geology, thirty-eight economic memoirs and thirty-six pamphlets on mineral resources, and nine pamphlets on underground water supply have been published. In the thirty years between 1910 and the outbreak of the last War, sixty-nine one-inch maps and ten quarter-inch maps were colour-printed. Sales stocks were destroyed during the Second World War; but since 1945, in collaboration with the Ordnance Survey, every effort has been made to replace the lost maps, while continuing to publish new maps on the one-inch scale and many second revision coalfield maps on the six-inch scale.

As a result of growing recognition of the scope and national importance of the Geological Survey's work, increases of staff followed both World Wars. The most recent expansion is not yet complete enough to balance increased commitments. In Scotland, for example, extensive collaboration with the Scottish Division of the National Coal Board and with the North of Scotland Hydro-Electric Board, the annual incidence of some hundreds of inquiries from other government departments and the general public, and the work involved in republishing colour-printed maps destroyed by enemy action, have prevented the Survey from making rapid progress over the whole field of its activities. A. G. MacGregor

THE TRAINING OF UNIVERSITY TEACHERS

The question of the advisability and possibility of providing new recruits to university teaching with some initial guidance in the technique of their calling has been examined by S. Radcliffe, lecturer in German at the University of Bristol (*Univ. Rev.*, 28, No. 1; October 1955).

Unlike France, little attention has been paid to the technique of lecturing in Great Britain. In general, lecturers are conscientious about the matter of their lectures, but give little thought to their form or their delivery.

That this can have a detrimental effect on students' work was borne out recently in the Vice-Chancellor's report for 1954–55 to the Convocation of the University of Liverpool. In examining the causes of failure among students taking university examinations, he includes, among "matters about which our consciences ought to be troubled", the following point: "the presentation of a subject in the lecture room, though impeccable as regards content, does on occasion leave much to be desired in the matter of elementary teaching techniques".

This is the most vital point of all. The cause of so much dissatisfaction quite often proves to be some fault in the technique of presentation, or even a mere mechanical shortcoming, which could in most cases so easily have been circumvented by some initial instruction and guidance of the lecturer concerned.

Radcliffe does not claim that teaching is a mechanical craft to be learned in a workshop, but suggests that an artist requires some basic instruction, at least in the rudiments of his craft.

The following are a few of the purely mechanical skills which might be considered desirable in a good teacher or lecturer. First, the adoption of a fitting speed and clarity of diction. Secondly, the clear formulation and appropriate stressing of the main points of the subject under review. Thirdly, the ability to use a blackboard successfully. Fourthly, the 'staging' of material to make it come 'alive'. The correct lighting and ventilation of the lecture room are of importance. A few weeks teaching in any school will bring these and many allied points home.

What is a fitting speed and clarity of diction? How many lecturers ask their students whether they can hear clearly, or whether they are speaking too quickly for them? A teacher can soon learn the correct measure in these instances with the aid of a little guidance. The undue dropping of the voice at the end of each sentence, for example, can produce both monotony and inaudibility. A person with a weak voice can be shown how to make the most of it by someone trained in these matters. This is a problem faced by teacher-training departments.

The clear formulation and appropriate stressing of the main points of the subject cover a large number of factors. Just as the potential teacher must learn how to arrange and present the various points he is intending to convey in a lesson, so must the lecturer have a clear and systematically arranged plan of what he intends to talk about. He must know which points are important or difficult enough to require particular stressing either in the form of repetition or slower and more deliberate speaking, or even by the dictation of vitally relevant matter.

The extent to which the blackboard is used will obviously vary with the nature of the lecture; a statistical, technical or linguistic theme will call for more blackboard writing than, say, a literature or philosophy lecture. Titles of works, proper-names, unusual or foreign terms, dates—all these should be written up to ensure that students get the correct form. The writing must be clear and legible, and not scattered about in disorder on the board.

Lastly, Radcliffe elucidates his reference to the proper 'staging' of material. There is an element of the histrionic in all personal teaching; the teacher is to some extent an actor, who must make his material come to life. There are some generally recognized devices into the application of which the tyro could with advantage be initiated. A slight break before passing on to a new theme in a lecture can be most refreshing for all concerned. An occasional pause to receive questions from students will in certain cases add to the effectiveness of the lecture; it "draws the students in" more and gives the lecturer a chance to gauge their grasp of what he is saying. Learning the students' names is an essential requirement in establishing such closer contact with them. The prompt return of written work not only helps to keep up students' interest in their subject, but also gives the right to demand written work from the students within the time-limit specified.

MORPHOGENETIC STUDIES OF *DRYOPTERIS*

In two studies, the growth, organization and morphogenetic activity of the shoot apex of *Dryopteris aristata* have been further investigated by experimental means. C. W. Wardlaw and E. G. Cutter (*Ann. Bot.*, 19, 76, 515; 1955) have observed that when the apical cell-group is damaged, leaf primordia, which may be orientated abnormally, continue to be formed on the meristem; but one or more buds may also arise. The observations reported here indicate that a zone at the periphery of the apical meristem is particularly reactive when the apical cell group is damaged, the majority of buds being induced in this region. The extent of damage to the apex may affect the sequence of organogenesis: when damage is extensive buds tend to be formed immediately, subsequent primordia developing as leaves; when the damage is confined to the apical cell, or extends to only a few of its segments, bud formation tends to be delayed. It is concluded that the effect of the apical cell on organ formation is exercised through the growth and organization of the apex as a whole.

E. G. Cutter (*ibid.*, 485) has also observed that in the shoot apex in *Dryopteris aristata*, maintained under conditions of progressive starvation for periods up to a year, the apex decreases very markedly in size; the size of leaf primordia at their inception decreases, but their size relative to the shoot apex increases; the rate of inception of leaf primordia decreases; the rate of morphological development of leaf primordia increases; there is a reduction in the system of phyllotaxis towards that characteristic of sporelings; the vascular system of the attenuated axes is dictyostelic, but there is a reduction in the number of meristeles in the axis and in the leaves.

THE SCIENTIFIC CIVIL SERVICE

PROMOTION OF INDIVIDUAL RESEARCH WORKERS

SPECIAL posts have been created in the Scientific Civil Service, as in previous years, under provisions included in the White Paper (Cmd. 6679: 1945), designed to provide for the promotion of individual research workers of exceptional merit. The promotions are effective from July 1, 1955.

Chief Scientific Officer

Dr. P. B. Walker spent five years as a designer in the aircraft industry after postgraduate research in the University of Cambridge on fluid motion. Then in 1935 he joined the Royal Aircraft Establishment, Farnborough, and was a pioneer of the rational scientific approach to aircraft structural design in place of the old empirical formulæ. During the Second World War he was responsible at the Ministry of Aircraft Production for the supervision of the design of gliders and paratroop aircraft. Dr. Walker returned to the Establishment in 1945 as head of the Structures Department, where he concentrated on building up first the Flutter Division, and secondly the Aircraft Structural Fatigue Division, into flourishing teams with widespread reputations. In particular, his work on aircraft fatigue was of great importance in connexion with the investigation of the Comet aircraft, for which he was made C.B.E. In 1951 he delivered the Wright Brothers Lecture in Washington, D.C.

Deputy Chief Scientific Officers

Mr. E. H. Cooke-Yarborough entered government service in 1940 and worked on the development of airborne radar. Later he concentrated on radio counter-measures and also on guided weapons. In 1946 he became interested in atomic energy, and eventually joined the Atomic Energy Research Establishment, Harwell, where he is at present deputy head of the Electronics Division. Mr. Cooke-Yarborough is well known as a specialist in the design of electronic circuits, and during recent years he has been associated with the design of digital computers and the use of transistors; a new computer employing transistors as circuit components is now in use at Harwell.

Mr. B. Sykes joined the Royal Aircraft Establishment, Farnborough, in 1925 from the Imperial College of Science and Technology, London, and his early work was in the field of aircraft electrical engineering, covering such problems as electrically heated flying clothing and the design of a self-regulating generator for aircraft. During the Second World War he played a considerable part in the design and setting up for production of predictor gunsights, and since the War he has been increasingly concerned with general problems of air fighting.

Dr. P. C. Thonemann graduated from the University of Melbourne in 1940 and worked first at the Munition Supply Laboratories, Victoria, and then at the Research Laboratories of Amalgamated Wireless of Australasia, where he was concerned with propagation problems. Later he gained a Commonwealth research fellowship at the University of Sydney, studying physical phenomena in ionized gases, and assisted in the development of gas-discharge modulator switches. At the Clarendon Laboratory, Oxford, he continued to study gas-discharge phenomena and their applications in nuclear science, and this led to the production of the radio-frequency type of proton source which is now used almost universally in laboratories equipped with high-voltage sets for the acceleration of ion beams. Since 1949 he has directed the work of a group investigating the properties of highly ionized gases.

Dr. D. Williams entered the Royal Aircraft Establishment, Farnborough, in 1924 from industry, where he had served as a pupil apprentice after graduating in mechanical engineering from University College, Cardiff, in 1922. Following a few years on stress calculations and the supervision of experimental aircraft contracts, he began work in 1930 on aeronautical structural research. During recent years his research has covered a wide field, including the first complete mathematical theory of 'sandwich' construction, the response of aeroplane structures to dynamic loading, aero-elastic calculations, pressure-cabin problems, and the dynamic instability of systems incorporating pneumatic-tyred wheels.

Senior Principal Scientific Officers

Mr. G. K. Adams graduated in chemistry from the University of Bristol in 1942 and then joined the Armament Research Department of the Ministry of Supply, where until the end of the Second World War he worked on the thermal decomposition of explosives and the evaluation and combustion of pyrotechnic compositions. In 1946 he joined the Explosives Research and Development Establishment, where he has carried out theoretical and experimental researches on combustion processes, especially on rates of flame propagation and of chemical reactions in flames.

Mr. R. Benjamin graduated in 1944 from the Imperial College of Science and Technology, London, and immediately joined the Admiralty Signal and Radar Establishment, where he is still serving. He has been mainly concerned with research in the fields of radar and electronics, and is the author or co-author of some ninety scientific reports and memoranda ranging from circuit design to the evolution of complete new radar systems. For security reasons the more important of his researches have not yet become available for open publication; but his theoretical ability and his exceptional skill in the practical solution of complex electronic problems are well known among workers in this field.

Mr. G. F. Clarke entered the electronics industry on graduating from the University of Birmingham in 1928, and after holding several posts he joined the Bawdsey Research Station in 1938, whence he went to the Radar Research and Development Establishment. Eight years later he transferred to the Royal Aircraft Establishment, where much of his work has been concerned with radar and guided weapons, but has not been published. As an investigator and adviser on widely varied problems, his knowledge combines both theory and practice.

Mr. D. R. Davies graduated in chemistry from University College, Cardiff, in 1924 and held a number of appointments in biochemical and medical research covering such subjects as the biochemical aspects of mechanisms of detoxication, brain enzyme systems with particular reference to narcotics, the metabolism of drugs in abnormal mental states, phosphatase of spleen and blood, and studies of physique and mental disorders. During the Second World War he held a commission and worked for the War Office on the analysis of causes of casualties and assessing the efficacy of therapeutic measures. He joined the Chemical Defence Experimental Establishment in 1947, where he has built up a flourishing biochemical section and has become a leading authority on the cholinesterases and their inhibitors.

Mr. R. A. Fairthorne joined the Royal Aircraft Establishment, Farnborough, in 1927, and six years later gained a first-class honours degree in mathematics as a result of private spare-time study. Of the many facets of his work, mention may be made of his studies on scientific and mathematical films, library organization and bibliography, the use of commercial punched-card techniques for scientific computing purposes and the application of statistical methods to aeronautical research. During recent years his notable work has been done on the theoretical principles underlying the handling, classification and communication of technical information.

Dr. A. F. Gibson joined the staff of the Telecommunications Research Establishment, Malvern, after graduating in physics from the University of Birmingham in 1944, but remained at Birmingham for research on luminescence in solids in collaboration with Dr. G. F. J. Garlick. He went to Malvern in 1948, working originally on infra-red photo-conductors, and in 1951 he took charge of the newly formed transistor physics research group. He is an outstanding experimentalist, equally at home in both pure and applied physics.

Dr. G. N. Harvey began his career as an officer in the Royal Navy, in which he again served during the Second World War, having in the meantime acquired both business and industrial experience. During his naval service he was closely associated with degaussing and was made O.B.E. In 1945 he joined the Admiralty Compass Department and worked on the theory and correction of errors in compasses. In 1947 he joined the Fighting Vehicles Research and Development Establishment, and there he has made important advances in such different fields of applied research as optics, navigational systems and servo-mechanisms.

Mr. C. E. Hubbard first went to the Royal Botanic Gardens, Kew, in 1920 as a student gardener and soon after became a technical assistant in the Herbarium under Dr. Otto Stapf, an authority on grasses. On the latter's retirement, Mr. Hubbard was appointed to take charge of this group, which he has made his special study ever since. He spent six weeks studying the flora in Spain in 1924 and a year in Australia during 1930–31 to assist the Queensland Government in the study of the indigenous grasses. He was made O.B.E. for services to science and agriculture in 1954.

Dr. J. L. King joined the Admiralty Research Laboratory in 1942 after studying mathematics in the University of Cambridge, and four years later was assimilated into the newly formed Royal Naval Scientific Service. Dr. King is the author of some twenty scientific reports ranging in subject-matter from hydrodynamics to atomic weapons, most of which, however, have not been published because of security regulations. One notable exception is a dissertation "On the Motion of an Elastic String", which is a basic study related to aircraft catapults. In the near future Dr. King will be returning to the hydrodynamics field as leader of a team which will be primarily concerned with fundamental theoretical investigations into the motion of bodies under water.

Dr. W. J. Kramers studied chemistry at the University of Oxford, and before joining the Ministry of Supply in 1949, he held appointments in industry and at the British Coal Utilization Research Association. His work in the Armament Research Establishment, and more recently the Atomic Weapons Research Establishment, is centred on the development of new ceramic materials. He was responsible for the development and preparation of cerium monosulphide—a material which had not been studied in Britain previously—and other novel ceramic compositions including various metal oxides; this latter work has led to the possibility of developing new high-temperature ceramics.

Dr. F. P. O. Kubaschewski joined the National Physical Laboratory, Teddington, in 1947, where he has made thermodynamical investigations concerning the possibilities of new methods of producing titanium, vanadium and zirconium. He has also been interested in the thermochemistry of metallic alloys in relation to the phase equilibria existing in metallic systems, and has developed novel methods of measuring directly the heats of formation of alloys in the solid state which are of importance in connexion with the mechanism of bonding. He is the joint author, with Mr. E. Ll. Evans, of "Metallurgical Thermochemistry" and, with Mr. B. E. Hopkins, of "Oxidation of Metals and Alloys".

Mr. W. Lawrence took the Mechanical Sciences Tripos at the University of Cambridge in 1926, and then spent several years in radio transmission work in industry. He joined the Signals Research and Development Establishment of the Ministry of Supply in 1941, where he worked originally on the development of mobile telecommunications equipment, and later on cables and special measuring apparatus. During recent years he has been concerned with research on data transmission and speech problems, and in the field of speech synthesis, in particular, his scientific understanding and experimental skill have led to notable advances.

Dr. Roy Markham joined the staff of the Agricultural Research Council Virus Research Unit in 1940 after graduating from the University of Cambridge. His work has been mainly concerned with the biochemistry of viruses, and in particular the function of nucleic acids in virus nucleo-proteins. He has been responsible for the development of a number of techniques for the analysis of nucleic acids and the determination of their structure.

Mrs. B. Naylor, who is a graduate in electrical engineering of the University of Manchester, entered the Royal Aircraft Establishment, Farnborough, in 1936, where for much of her career she has been concerned with research on aircraft engines and accessories and test-plant for them. During more recent years she has worked on combustion problems, on ram-jet development, and on the cooling of supersonic aircraft. She is a qualified pilot and therefore brings first-hand knowledge to the aircraft problems with which she deals. She was made O.B.E. in 1949.

Dr. K. P. Oakley, of the Department of Geology, British Museum (Natural History), is an authority on human and near-human fossil remains, his handbook, entitled "Man the Tool-Maker", on the British Museum's post-war exhibition on man as a tool-making primate being widely used in British and American universities. In co-operation with the staff of the Government Chemist's Department, he has investigated the geological age of a number of fossil human remains of disputed age by fluorine-dating and other methods, and has obtained some remarkable results. In 1953 Dr. Oakley investigated fossil Hominid sites in South Africa and obtained data bearing on the age of the Australopithecines and the Rhodesian and Saldanha skulls.

Dr. G. M. Roper studied mathematics at Cambridge and then was a school-teacher for several years before becoming a mathematics lecturer at the Chelsea Polytechnic in 1941. After doing aerodynamics research in her spare time at the Imperial College of Science and Technology, London, for which she gained a Ph.D., she joined the Royal Aircraft Establishment in 1941, where, in addition to being in great demand as a mathematical consultant, she has done valuable research in the theory of supersonic flow, especially in the study of delta and swept-back wings.

Dr. W. B. Thompson graduated in mathematics and physics from the University of British Columbia in 1945 and later gained his Ph.D. at the University of Toronto for a thesis on thermal convection and the Earth's magnetic field. After part-time research at the Chalk River Laboratories on the energy distribution of plutonium fission fragments, he went to Britain with a senior research fellowship at Harwell, where he has been mainly concerned with the theoretical analysis of the physical properties of highly ionized gases. In addition, he has published papers on thermal conduction in magnetic fields and on the acceleration of cosmic-ray particles.

Dr. D. P. Wilson has been engaged in research at the Plymouth laboratory of the Marine Biological Association since 1926. He first studied extensively the development of polychaete worms, and this led him to examine the external factors controlling settlement and metamorphosis. He has also shown that sea water from some areas is less favourable for larval development than that from others, thus making more understandable the regional differences in the distribution of different species of bottom-living animals. Dr. Wilson is a graduate of the University of Manchester, gaining his doctorate in 1949.

Mr. F. P. W. Winteringham's work at the Pest Infestation Laboratory of the Department of Scientific and Industrial Research has led to the application of radioactive tracer and paper-chromatographic techniques to two lines of investigation concerned with the use of insecticides in the protection of stored foodstuffs: the contamination of food resulting from treatment with fumigants and contact insecticides; and the study of insecticidal action within the body of the insect. In connexion with the latter it has been found possible to label not only the insecticide under investigation but also the enzymes and metabolites in the living insect. This makes it possible to isolate and determine quantitatively, by chromatographic techniques, the component parts and by-products of different metabolic cycles, first in the normal insect and then in the insect affected by the insecticide.

OCCURRENCE OF *BEIJERINCKIA* SPECIES IN THE 'PHYLLOSPHERE'

By Dr. J. RUINEN

Treub Laboratory, Kebun Raya Indonesia, Bogor

In 1949 Derx[1,2] started an investigation into the occurrence of nitrogen-fixing organisms in tropical soils—a question up to then much disputed; but after incidental research in the first half of the century once more of importance in view of the increasing need of fertilizers in a region notoriously poor in nitrogen. After establishing the carbohydrate source and *p*H required for their culture, Derx succeeded in isolating a number of nitrogen autotrophic bacteria from soil and water, namely, *Azotobacter chroococcum* Beijerinck, *A. vinelandi* Lipman, *A. agilis* Beijerinck and *A. indicum* Starkey et De. The last-mentioned species was segregated from the others and placed in the new genus *Beijerinckia* because of differences in the physiological, cultural and morphological properties. The presence of *B. indica* (Starkey et De) Derx and *B. mobile* Derx has been demonstrated in the acid and slightly alkaline soils of Indonesia, of Nigeria, of the savannahs of the Belgian Congo, of the upland rice-fields in Tonga, and of the rice-fields of Surinam[3]. A similar occurrence was reported by Kluyver and Becking[5]. Besides the first isolations from Indian[6] and Malayan[7] soils, the presence of *Beijerinckia* in soils in the tropics, in particular North Australia, was reported by Tchan[8], while Döbereiner cultivated many strains of *Azotobacter*[9] and *A. indicum*-like organisms abundant in acid Brazilian soils (personal communication). *Beijerinckia* has never been reported outside the tropics. It could not be isolated from the soils of temperate zones[5] or from the soils in nurseries in Holland where tropical conditions were maintained during the summer months. Derx[4] suggested that the occurrence of *Beijerinckia* might be due to a possible association with specific tropical vegetation, presumably leguminous plants, or rice, because cold storage does not affect the viability appreciably and the habitats so far reported are all tropical. Kluyver and Becking, on the other hand, pointed out that the prevalence of *Beijerinckia* in lateritic formations and not in other soil types may explain why until now it has been found only in the tropics.

During the period of Derx's research on nitrogen fixation I[10] was studying the interrelation between the different components of the epiphytic vegetation in Indonesia. The main object of these studies was a small epiphytic fern, *Drymoglossum piloselloides* Presl, common not only on trunks and branches, but also having a tendency to settle on leaves, to which it attaches itself by spreading roots and root hairs. Its occurrence in this habitat might be explained by the cuticular excretion of the leaves. It is a striking fact that trees overgrown by this epiphyte decline; and it was proved in a number of cases that fungi living in the rhizosphere of the fern infect the tree-support and cause the die-back of the branches.

In searching for the organisms which might be responsible for this decline and which might, eventually, account for the presence of higher epiphytes, an analysis was made of the rhizosphere-vegetation of the latter. During the years 1952–54 the relation between seven different tree-supports, including barks with rough and smooth surfaces, and ultimately the leaves, and two epiphytes was examined microbiologically. A routine comprising observation under low magnification and plate-culture was followed. Taking the limitations of the method into account, it nevertheless became evident that: (1) in the rhizosphere the fungi prevailed over the bacteria; and (2) in the adjacent areas the bacterial flora was richer. Microscopical observation showed that the fungi were mostly common soil fungi and mild parasites.

The second point, the prevalence of bacteria in the areas not covered by the epiphyte, was investigated in more detail. For this the anatomically simpler leaf surface seemed preferable to the complicated periderm. The same difference in microbe distribution was found. Moreover: (1) the fungal population increased with the age of the leaves; it was practically absent on young ones and became abundant on senescent ones; (2) the bacterial population similarly increased with age, becoming abundant as soon as the leaf was full-grown; (3) the ratio fungi : bacteria was lowest on the full-grown leaf, but appeared to increase on older leaves; (4) the species of bacteria and yeasts in the epiphyllic population seemed characteristic and limited in number; (5) among the bacteria *Mycoplana rubra* (Den Dooren de Jong) Derx et De Vries and *Beijerinckia* sp. occurred frequently; (6) the time of soaking and shaking the leaves before plating influenced the plate-count.

These observations suggested the existence of a characteristic milieu which is conditioned by the leaf, and may be called, in analogy with the rhizosphere, the 'phyllosphere'. (Since the completion of this communication I have seen the article on fungus incidence on cereal leaves in which Last also introduces the term 'phyllosphere' in the same sense (*Trans. Brit. Mycol. Soc.*, **30** (3), 221; 1955).)

As this phyllosphere apparently is a favourable habitat for *Beijerinckia*, more leaves were examined. Leaves from trees and shrubs of different ecological groups collected in different localities in Java, Sumatra and Banka were studied. The sources of the material comprised trees up to 24 m. in height, free-hanging tendrils of climbers, crater-plants, epiphytes and coastal vegetation. The epidermis was examined directly under 900 times magnification. Furthermore, a simple bacterial enrichment technique was used—virtually a modification of Winogradsky's starch method. In 192 out of 196 cases *Beijerinckia* was observed. In a saturated atmosphere at room temperature (varying from 26° to 32° C.) the bacteria appear within twenty-four hours; later they become overgrown by other bacteria, yeasts and fungi, but when this vegetation declines after having exhausted the original medium, *Beijerinckia* colonies emerge from the debris.

The apparent omnipresence of *Beijerinckia* on leaves as a component of a typical vegetation, characterized *inter alia* by a number of slime-producing organisms, opens a new field of tropical botanical and microbiological research.

The importance of the nitrogen-fixing property of *Beijerinckia* has already been demonstrated in the ecological relationship with blue-green algae in rice-fields. It may prove to be still more important in the phyllosphere. It seems quite plausible on one hand that the stream of nutrient salts and metabolites excreted by the cuticle serves as the nutrient medium of the epiphyllic micro-vegetation, while on the other hand the nitrogen fixed by *Beijerinckia* might offer a constant and essential source of bound nitrogen. The latter may be taken up directly by the leaves in the diurnal rhythm of water-content variation, and then transported through the plant body itself. It also may be washed off by the rain together with the leaf excretions and via the soil reach the ordinary upward nutrient stream. A second cycle of nitrogen-fixation in the soil and decomposing leaf litter may support the first-mentioned one.

This may imply that the inexhaustible reserves of atmospheric nitrogen and carbon dioxide in conjunction with the climatic conditions are ultimately the cause of the luxuriant tropical vegetation through the interrelationship of these bacteria and the green plants. Eventually it might explain the wide distribution of *Beijerinckia* throughout the tropics. A closer study of the phyllosphere and the occurrence of *Beijerinckia* and other micro-organisms in this milieu will be important for agriculture and forestry.

The preliminary work and further considerations on this problem will be published in the *Annales bogorienses*.

SPECTROCHEMICAL ANALYSIS WITH TIME-RESOLVED SPARK SPECTRA

By DR. Á. BARDÓCZ and F. VARSÁNYI

Department for Spectroscopy, Central Research Institute for Physics, Hungarian Academy of Sciences, Budapest

IT is well known that the main advantage of the high-voltage electric spark as a spectrochemical light-source is that its analytical accuracy is in general the highest of all light sources. Its disadvantage, however, is that its sensitivity is low, which is mainly due to the fact that the spectrum of the electric spark has a continuous background, in which weak spectral lines cannot be observed. Even if the spectrum line/background ratio is high, the background is still highly disturbing in the evaluation of intensities.

It is known from earlier investigations that the background of spark spectra appears in the initial stage of the discharge; in the subsequent stages of the spark the spectrum is practically free from background. Steinhaus, Crosswhite and Dieke[1] introduced a photoelectric procedure, by means of which this background can be separated from the spectrum. We have developed a method by which the background is separated by optical means. This method is capable of giving spectra practically free from background. To this end a high-precision spark source and an optical arrangement containing a rotating mirror are needed. The spectrum may be detected either photoelectrically or photographically.

The optical arrangement is shown in Fig. 1. The reduced image of the light source *A* is formed on the slit *S*2 by means of the concave mirror *M* fastened to the shaft of the synchronous motor *C*. The slit *S*2 is parallel to the plane of the figure, and selects a part of the time-resolved image of the light source. An image of the slit *S*2 for the collimator lens of spectrograph *D* is obtained by means of lens *L*. *S*1 denotes the slit of the spectrograph and *P* the photographic plate.

As the production of a single spectrum requires an exposure of a few minutes, that is, the light of several thousand spark discharges, in order to obtain the result desired, the time-resolved image of the individual sparks must be precisely formed at the same point of the plane of slit *S*2. In other words, the problem requires the precise synchronism of the rotation of the mirror and the initiation of the individual spark discharges. The problem is solved by means of the electronically controlled spark-source introduced by Bardócz[2], in which the spark discharge is initiated with a jitter of a few tenths of a microsecond with respect to a controlling signal. The spark source is controlled by the amplified voltage signal of photocell *I* illuminated by the lamp *H* at each turn of the rotating mirror *M*.

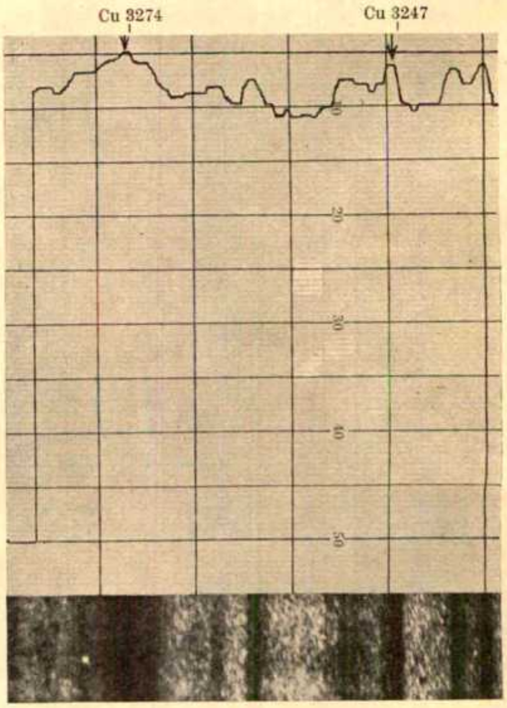

Fig. 2. Lower part: Cu 3274 and Cu 3247 lines in the spectrum of aluminium containing 0·01 per cent copper. Upper part: density curve of the above spectrum as scanned by a recording microphotometer. Magnification of the spectrum, 25 ×

The image of the light-source *A* is adjusted on the slit *S*2 by setting the lamp *H* or the photocell *I* perpendicular to the plane of the figure.

To illustrate the advantages which can be achieved by the above procedure in spectrochemical analysis, Fig. 2 shows part of the spark spectrum of aluminium containing 0·01 per cent of copper, taken in the usual manner, with background. The upper part of Fig. 2 shows the density curve of the spectrum scanned by a recording microphotometer. Fig. 3 shows the same part of the spectrum as photographed by the method described here. The difference between the line density/background density ratios in the two figures is striking. The deflexion of 50 is in both cases that corresponding with the unexposed plate.

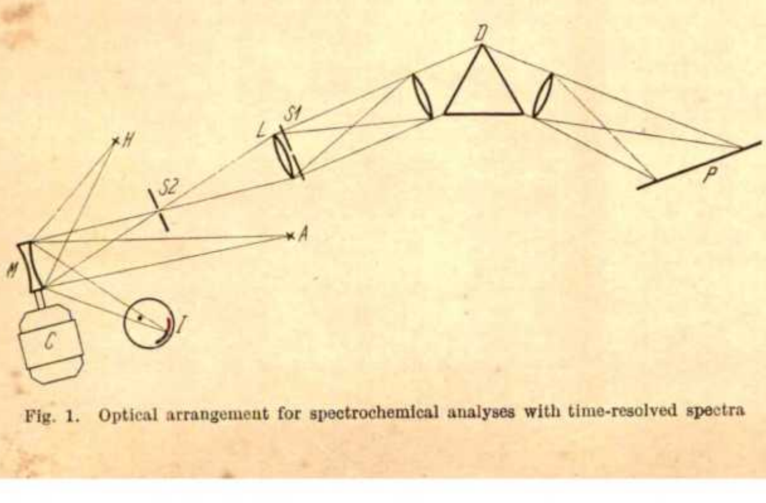

Fig. 1. Optical arrangement for spectrochemical analyses with time-resolved spectra

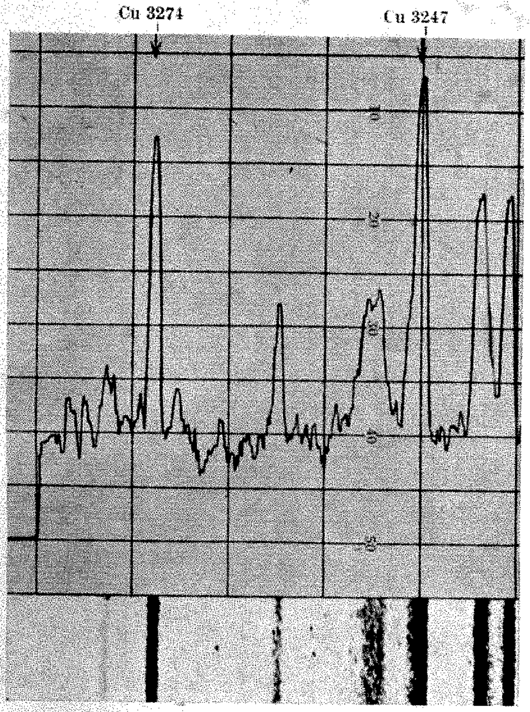

Fig. 3. Lower part: Cu 3274 and Cu 3247 lines in the time-resolved spark spectrum of aluminium containing 0·01 per cent copper. Upper part: density curve of the above spectrum as scanned by a recording microphotometer. Magnification of the spectrum, 25 ×

In taking the spectra of Figs. 2 and 3, the capacity of the condenser of the spark source[2] was 10,000 pf., its charging voltage 20,000 volts, and the frequency of the spark 50/sec. One of the electrodes was aluminium rod containing 0·01 per cent copper and other impurities, and the other a spectroscopically pure carbon rod. The electrode separation was 3 mm. The photographs were taken with a medium-size spectrograph, on Agfa Blau rapid plates. The slit width of the spectrograph was 30 microns. The exposure time of Fig. 2 was 1 min. and that of Fig. 3, 4 min. These exposure times were chosen so that in both spectra the strongest density should be about the same.

The photographs reproduced in Figs. 2 and 3 were taken with the same equipment, except that in the case of Fig. 2 the mirror was still, whereas in the case of Fig. 3 it rotated with a frequency of 3,000 revolutions/min. One side of the mirror was coated with aluminium and the other with dull black paper. The distances *A–M* and *M–S*2 were 403 mm. and 325 mm. respectively. The radius of curvature of the mirror is 360 mm. The travelling speed of the image of the light source on the screen *S*2 was 0·204 mm./microsec. In taking Fig. 3, the light emitted by the spark between 29 and 54 microsec. was used.

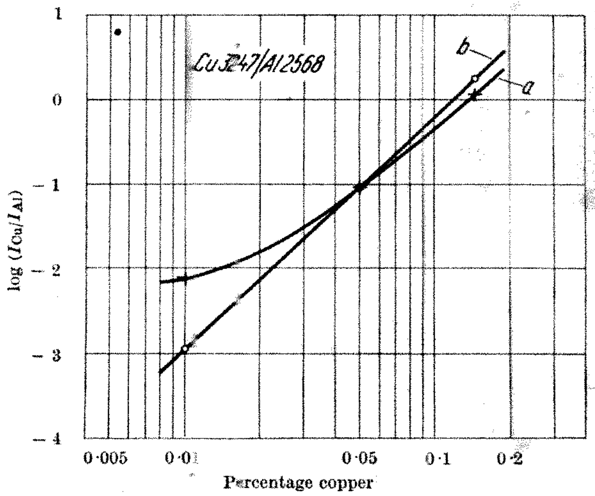

Fig. 4. Analytical curves for the determination of copper in aluminium. Curve *a*: taken in the usual manner. Curve *b*: initial stage of the discharge cut out

Fig. 4 shows two analytical curves for the determination of copper in aluminium. One of the curves (*a*) was taken in the usual manner and the other (*b*) with the initial stage of the discharge cut out. The Cu 3247 and Al 2568 lines were used for plotting the analytical curves. [July 23

PAPER CHROMATOGRAPHY OF INSULIN

PREPARATORY to carrying out experiments on the incorporation of labelled amino-acids into insulin in beef pancreatic slices, it was necessary to design some method which would allow of the isolation and determination of the insulin in small amounts of tissue with reasonable accuracy and speed. In view of the rather unusual solubility properties of this protein, it appeared possible that some chromatographic separation might be feasible. Several investigators have carried on work of this kind. Porter[1] separated pure insulin from crude preparations by using a silane-treated silica gel column; Porath and Li[2] used a charcoal column successfully. Others have tried to separate various proteins by paper chromatography. Sanger[3] did not obtain notably good results with insulin fractions *A* and *B* because of streaking. However, Robinson and Fehr[4] were able to estimate the percentage of insulin in protamine insulin by using the upper phase from a butanol/acetic/water (3 : 1 : 4) mixture as a chromatographic solvent.

After trying various solvent combinations, we likewise found it possible to isolate insulin from the major part of the contaminating protein by using a similar mixture of butanol, water and acetic acid in a single phase. Insulin on the paper was then determined by staining and reading the depth of colour of the eluate as described below. The preliminary extraction and purification of insulin were carried out by standard methods, with slight modifications[5].

The proteins in about 1 gm. of hashed tissue were precipitated by the addition of 25 ml. of 6 per cent trichloracetic acid. After homogenization, the protein was centrifuged down and washed with trichloracetic acid (5 per cent, 1 ml.). The precipitate was extracted twice at 37° for 2 hr. by shaking with

4-ml. portions of an acidic solvent (15 ml. ethanol, 5 ml. water and 3 ml. concentrated hydrochloric acid), and the *p*H of the combined extracts was adjusted to 8·5–9 with concentrated ammonium hydroxide, after which they were allowed to stand in the cold. Any precipitate was discarded after washing with ammoniacal alcohol. Insulin in the alcoholic solution (about 10 ml.) was precipitated by the addition of about 40 ml. of an alcohol–ether mixture (3 : 5 by volume), and allowing to stand in the refrigerator. After washing this precipitate of crude insulin with alcohol, the soluble part was taken up in 0·3 ml. of the acidic solvent, to which was added 0·1 ml. of 0·1 *N* hydrochloric acid; the total volume then being of the order of 0·5 ml.

This solution was applied to a curtain of Whatman 3 *MM* paper (46·5 cm. × 67 cm.) as a streak of droplets on a line 7 cm. from the upper edge of the paper, dried in air, and chromatographed for 10–12 hr. with a fresh mixture of butanol, water and acetic acid (12 : 5 : 2 by vol.). It has been found advisable to add all the solution in the original streak. If the atmospheric conditions change, the water content of the paper may vary, so that some slight modification in the solvent may be necessary. Under the conditions described, the insulin moves with R_F 0·21 approximately.

After drying the paper at 40°, it was dyed in a tray for 10 min., using a mixture of bromphenol blue 0·05 per cent, mercuric chloride 1 per cent, and acetic acid 2 per cent. Dilute acetic acid was then used to wash out all the excess dye. The insulin streak was cut out and reduced to shreds, which were packed into a small tube to which was added 25·0 ml. of the acidic solvent. After extracting for 45 min., samples were removed, centrifuged to get rid of any paper and the depth of colour determined at 470 mμ. The actual amount of insulin was determined by comparing the colour with that from insulin standards treated in exactly the same fashion. A linear relationship existed between the amount of dye eluted and the amount of insulin applied to the paper in the range 0·1–2·0 mgm. of insulin.

The results of chromatographing liver proteins against insulin with five different solvent systems are shown in Fig. 1. This provides the reason for the selection of the solvent system used. It also indicates that there is probably no significant amount of other protein in the liver extract which behaves like insulin when the proper solvent combination is used. None of a series of other proteins tried, including ribonuclease and serum proteins, behaved as did insulin; although there are indications that glucagon may have very similar properties.

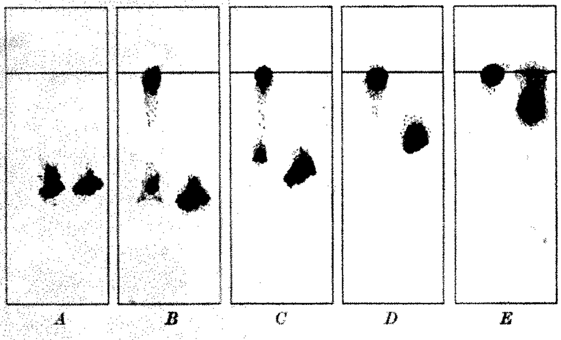

Fig. 1. Chromatography of insulin and extracts of liver. The left-hand spot of each pair is insulin. The solvent mixtures are made up with the following proportions of butanol, water and acetic acid: *A*, 6 : 2 : 0·64; *B*, 6 : 3 : 1·2; *C*, 6 : 4 : 1·52; *D*, 6 : 5 : 1·72; *E*, 6 : 6 : 3·4. All solvent systems comprised a single phase

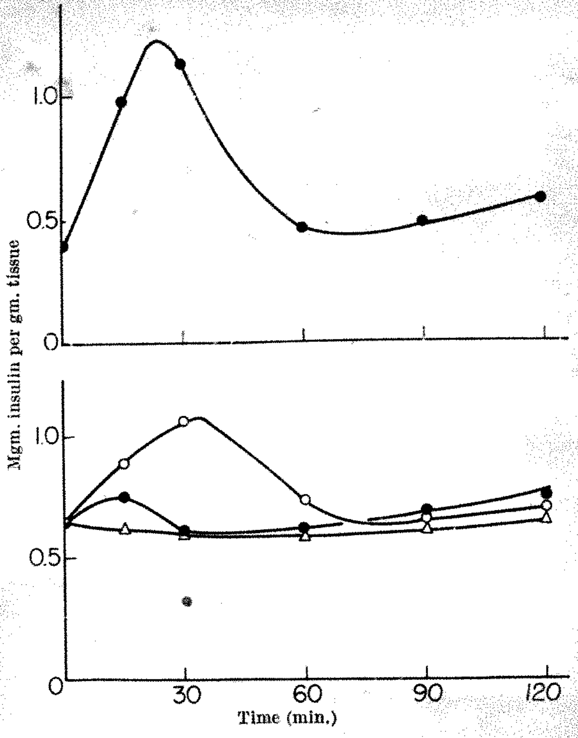

Fig. 2. Changes on insulin content of fœtal beef pancreas following incubation under various conditions

Upper curve: Incubation in 95 per cent oxygen, 5 per cent carbon dioxide. Lower curves: open circles, conditions as for upper curve; closed circles, incubation under 95 per cent nitrogen, 5 per cent carbon dioxide; open triangles, under oxygen in the presence of 10^{-4} *M* dinitrophenol

When insulin was added to an acidic solvent-extract of liver, prepared as indicated above, the recovery of the insulin varied between 92 and 93 per cent, the acidic extract itself containing no detectable amount of the hormone. Insulin recovered from chromatograms was biologically active and when subjected to electrophoresis on paper using veronal buffer (0·05 *M* at *p*H 8·6) it behaved precisely as did insulin.

1-gm. samples of fœtal beef pancreatic slices were incubated in the pyruvate–bicarbonate buffer (*p*H 7·6) described by Anfinsen[6] and the changes in insulin content over a period of two hours at 37° were measured by the method just described. Fig. 2 shows the results when the incubations were carried out in the presence and absence of oxygen and with the addition of dinitrophenol. With oxygen present, the insulin content of the tissue increased during the first 30–40 min. of incubation, but later there was a decrease. In the absence of oxygen no such phenomena occurred. Whether these results are to be attributed to the net synthesis of insulin during the first part of the incubation period, or to the formation of insulin from some precursor, is not clear.

When slices were incubated for 30 min. in the presence of 0·2 per cent glucose, there was an increase in insulin content of 65–72 per cent. Glucose appeared to have a direct effect on insulin production by slices, as it has on the perfused pancreas[7]. Work is in progress to determine if this is an effect of synthesis or secretion, and to determine the effect of other carbohydrates and hormones on insulin production.

This investigation was supported in part by a grant from the United States Public Health Service.

In the course of the development of a procedure for the small-scale isolation of labelled insulin from surviving pancreas slices, a rapid method for the detection of this protein in crude pancreas fractions was required. It was found that the presence of insulin in these fractions could be demonstrated by the use of paper chromatography, and that protein contaminants, when present, were readily detectable in the more highly purified insulin samples. Moreover, further studies showed that this chromatographic procedure was suitable for routine use as a preparative method which then replaced the lengthier procedures[1,2] originally investigated. Hitherto, only the paper chromatography of pure crystalline insulin[3] and pure protamine insulin[4] have been reported.

A large number of solvent systems were tested with crystalline insulin on Whatman No. 1 paper, using descending chromatography. Results obtained with the satisfactory systems are reported in Table 1. In most cases, systems containing 2-butanol gave excellent results, with 2-butanol/1 per cent (v/v) acetic acid (1 : 1) giving the most discrete spots. 20 µgm. of insulin is easily detectable. Some of the properties of this system for crystalline insulin and for crude and partially purified pancreas extracts are reported below.

The R_F of crystalline insulin in this system varies with the amount applied to the paper and with the distance travelled by the solvent front. The following R_F values were found for the corresponding amounts of insulin (given in µgm. in parentheses): 0·33 (200), 0·32 (160), 0·30 (120), 0·27 (80). The dependence of R_F on the distance travelled by the solvent was studied by spotting the insulin solution along an oblique line according to the method of Bowman[6]. The following R_F values were found for the corresponding distances (given in cm. in parentheses) travelled by the front: 0·30 (28·5), 0·29 (25·9), 0·26 (23·2), 0·24 (20·6), 0·23 (17·6), 0·23 (14·9). The R_F values at 6° and at 25° were the same. Ascending chromatograms gave substantially lower R_F values than descending.

Table 1. R_F Values of Insulin in Various Solvent Systems

Solvent system	R_F
2-Butanol/1 per cent acetic acid (1 : 1)	0·30
2-Butanol/1 per cent dichloracetic acid (1 : 1)	0·29
2-Butanol/acetic acid/water (4 : 1 : 5)	0·92
2-Butanol/formic acid/water (4 : 1 : 5)	0·90
1-Butanol/acetic acid/water (4 : 1 : 5)	0·29
Phenol/water (4 : 1)	0·95

The numerical ratios given in column 1 represent the proportions of the volumes of solvents which were mixed. Where two phases resulted, the organic phase was used and the aqueous phase discarded. 50 µgm. of insulin dissolved in 0·05 *N* hydrochloric acid was used in most cases. The positions of the spots were determined by the bromphenol blue method (ref. 5). Development was stopped when the solvent front had moved about 30 cm.

The paper chromatographic technique described here for pure insulin could be used to detect the presence of this protein in the various crude fractions obtained from the procedure of Romans *et al.*[1] provided that the sample to be chromatographed is first dialysed free of salt and that an excessive amount of crude protein is not put on the paper. The amount of insulin present could be estimated approximately by comparison with known insulin spots. Ribonuclease, serum albumin, or pancreas fractions depleted of insulin show no movement. However, crystalline glucagon moves at the same R_F as does insulin. Its presence in insulin samples may readily be detected by paper electrophoresis at *p*H 7·5[7].

For preparative purposes, a modification of the chromatographic procedure was necessary. In the presence of large amounts of non-insulin protein material, the movement of insulin is almost completely inhibited, even on the thicker Whatman papers; a development time of two days is necessary for even slight separation under these conditions. This difficulty could be obviated by using Munktell No. 20 electrophoresis paper, which permitted the insulin to move at its normal R_F, even when the paper was heavily loaded with crude material. In a large-scale experiment, 80 gm. of calf pancreas slices was incubated for 1·5 hr. in the presence of DL-leucine-1-^{14}C. After incubation, the pancreas slices and medium were lyophilized, extracted with acid-alcohol solution[1], the *p*H was adjusted to 6, and the proteins were precipitated with 2 volumes of ethanol and 4 volumes of ether. The precipitate was taken up in 0·05 *N* hydrochloric acid, and the soluble portion was dialysed against distilled water, concentrated, and streaked on to the paper. After elution of the insulin band with 0·01 *N* hydrochloric acid, the insulin was rechromatographed using the same system. A trace of protein remains at the origin. The yield of insulin after elution was 32 mgm. Evidence that the isolated insulin is pure, that it retains its biological potency, and that the labelled leucine is actually incorporated into the insulin molecule will be presented elsewhere[7].

This investigation was supported in part by a research grant (A-428) from the National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health, Public Health Service, and in part by an institutional research grant from the American Cancer Society. A Photographic Method for the Study of Insect Migration

THE study of the migration of swarms of the desert locust (*Schistocerca gregaria* Forsk.) has involved the detailed analysis of the flight behaviour of the individual locusts constituting a swarm. Following Gunn *et al.*[1], it has been shown that by placing a camera on the ground with the lens pointing upwards, it is possible to obtain photographs of locusts flying in a swarm which are 'readable' up to the limits set by the lens, the shutter-speed in relation to the ground-speed of the locust, and the emulsion used. These photographs have been useful for determining the orientation of individuals and also, from the size of the images and of a sample of the locusts under observation, the area-density and volume-density of the flying locusts in the layer of the swarm resolvable by the camera.

A further development of this technique, using a camera modified to give two images of each locust on each negative separated by a known interval of time, has made it possible to record also the track and ground-speed of the individual locusts. By including in the field of view of the lens a wind vane, and also recording the corresponding wind-speed, the air-speed of the flying locusts can be estimated. An *F*.24 aerial survey camera was used, with a focal-plane shutter and a control unit (type 35) which can be set to give exposures automatically at any time interval between 3 and 50 sec. on a 100-exposure film in an interchangeable magazine. A modified shutter-blind was made with two ⅛-in. slits instead of one, at a distance of 1½ in. from each other, giving at the appropriate tension the sequence 1/500 sec. exposure – 1/50 sec. interval – 1/500 sec. exposure. The interval of 1/50 sec. between exposures gave locust images usually separated clearly but not by too great a distance for the pairing of corresponding images. An electric counter of post-office type, recording the revolutions of an electric anemometer, was fitted to the camera in place of the usual clock recording system. With the automatic control taking photographs at known time-intervals, each photograph thus recorded the speed and direction of the wind as well as the course and track of each locust, for which both ground-speed and air-speed could be estimated. The material is still in course of analysis; it has been found to provide evidence not only of the behaviour of the locusts but also of the fine structure of turbulent air.

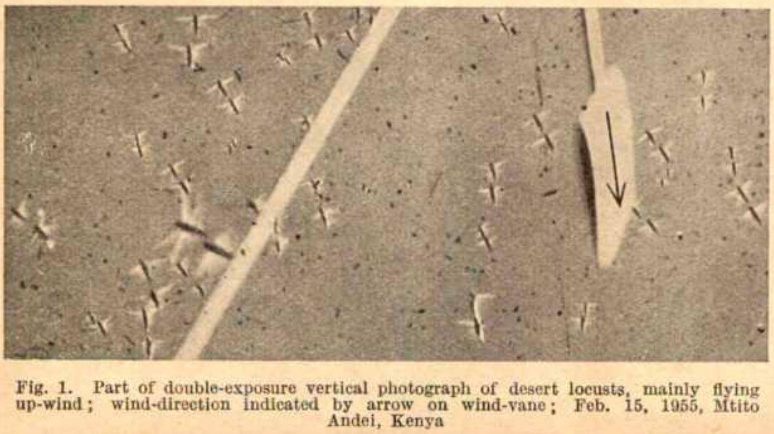

Fig. 1. Part of double-exposure vertical photograph of desert locusts, mainly flying up-wind; wind-direction indicated by arrow on wind-vane; Feb. 15, 1955, Mtito Andei, Kenya

Genetical Effects of Radiations from Products of Nuclear Explosions

PROF. J. B. S. HALDANE's letter[1] on the genetical effects of radiation resulting from nuclear explosions raises the question of the relative dose-rates to man and to *Drosophila melanogaster* arising from natural sources of ionizing radiations. It appears to have been generally assumed that the background dose-rates to the gonads of all species are identical, whereas they are likely to differ considerably. The gonads of the *Drosophila*, for example, are exposed to both environmental β- and γ-rays, but those in most mammals are screened entirely from external β-rays and partly even from γ-rays. In Haldane's argument, deductions about radiation effects in *Drosophila* appear to have been carried over to the human case without allowing for this difference.

The suggestion that the radiation dose needed to double the human mutation-rate is a little more than 3 r. per generation is based by Haldane on the following arguments, set out in his Croonian Lecture[2]:

(1) ". . . it follows that human mutation rates are about twice those of Drosophila per nuclear division and about one two-hundredth of those of Drosophila per day."

(2) "It has been calculated that natural radiations and particles of high energy will account for only 0·001 of the mutations in Drosophila".

(3) "It is clear that if so they may account for about a fifth of those in man, and in view of the uncertainty of our knowledge as to the efficiency of particles from K40 and cosmic rays in producing mutations, and the different radiosensitivity of different genes, it is quite possible that radiation may account for most human mutation."

No reference is given for statement (2), but the result quoted is that given by Lea[3], where the fraction 0·001 is deduced on the basis of the known number of mutations produced per unit dose in *Drosophila* and an estimated background dose-rate of 50 ionizations per c.c. per sec., or 2·2 mr. per day, giving 0·05 r. in the life-span of the fly. This dose-rate, given by Lea[3] as a "generous estimate" based on the measurement of the natural leak of ionization chambers, must by its magnitude include ionization due to external β-radiation. By comparison, the background dose-rate which affects human soft tissues, including the gonads, is about 0·26 mr. per day[4], amounting to the value usually quoted of 3 r. in thirty years. This is only one-eighth of the dose-rate used in the calculations on which the fraction of 0·001 in statement (2) is based and, if allowance for this is made in the argument of statement (3), the background radiation could account only for some 2·5 per cent of the human mutation-rate. Moreover, with regard to the role of potassium-40, the estimated dose-rate for man includes the radiation from the tissue content of potassium, the β-particles of which have approximately the same relative biological efficiency as γ-rays[5]. The proportion of the mutation-rate thus attributed to background radiation, namely, 2·5 per cent, is so much less than the figure of 20 per cent derived by Haldane in statement (3) that considerations other than the purely physical must be adduced if his contention that natural radiation accounts for most human mutation is to be supported.

It can be shown that, in this estimation of the fraction of the human mutation attributable to background radiation, the result depends only on the radiation-induced rate for *Drosophila* and the gonad dose to man. The dose-rate assumed for *Drosophila* determines the radiation fraction for that insect but does not affect the fraction estimated for humans. The argument in statement (3), based on the fraction for *Drosophila*, is only valid if the two species receive the same dose-rate.

In applying Russell's data[6] on radiation-induced mutations in mice to estimate the part played by radiation in human mutation, Muller[7] has also translated to the human case an estimated *Drosophila* background dose-rate of 0·045 r. in four weeks, getting, without further qualification, a gonad dose of 17·5 r. in thirty years. This figure is six times that usually taken as representative of areas of the world when the ground radioactivity is not exceptionally high, and is about four times the value which can be deduced from Sievert's results[8] for persons living in the average type of house in Stockholm, a region of admittedly high local radioactivity. Use of a generation-dose of 3 r. in Muller's calculation, however, leads to the conclusion that, in ordinary circumstances, about 4 per cent of the mutation-rate in man could be attributed to background radiation.

In the present lack of more detailed information, it might reasonably be taken that the gonad dose in man is due principally to cosmic rays, local γ-radiation and radiation arising from tissue potassium. The screening factor of tissues overlying the human gonads has not so far been determined, but, for local γ-radiation, it is probably about 2 when averaged for the male and female of the species. In *Drosophila melanogaster*, or other small insects, the dose from external β-radiation and perhaps also a contribution from α-radiation must be added to the γ-ray dose. Tissue potassium, however, will contribute little to the total because the β-particles of potassium-40, having mean ranges of 2 mm. in tissue, can leave only a negligible fraction of their energy in the organs of small dimensions in which they arise.

It is likely that more precise data will become available on the background dose-rates to man and to animal species used in genetical studies. Until then the above considerations would appear to be relevant to the assessment of the part played by background radiation in human genetics.

Note added in proof. Muller (*Bull. Atomic Scientists*, 11, No. 9, Nov. 1955; see *Nature*, Jan. 21, p. 103) has recalculated the fraction of the human mutation-rate attributable to natural radiation as lying between 8 and 16 per cent, on the basis of a gonad dose of 6 r. in 25–30 years. This gonad dose appears to be higher than measurements have so far indicated for regions outside known radioactive areas and is twice the value taken as representative for Britain.

[8] Sievert, R. M., and Hultqvist, B., *Acta Rad.*, **37**, 388 (1952).

I MUST thank Prof. F. W. Spiers for pointing out some of the errors in the basis on which I suggested in 1948 that most human mutations might be due to the action of photons or particles of high energy. Perhaps, however, he was not quite accurate in writing of my "contention that natural radiation accounts for most human mutation". I stated that this was "quite possible", and still hold that opinion. Further, his estimate of the dose received by *Drosophila* may be a little low, since the larvæ spend their life embedded in a medium containing appreciable amounts of potassium. Wright[1], in rough agreement with Spiers, has suggested that about 0·00015 of mutations in *Drosophila melanogaster* are due to radiation and rapid particles. Thus my provisional figure of 20 per cent should probably be reduced to about 2·5 per cent. But Russell[2] finds a mean mutation-rate at seven mouse loci of $2\cdot5 \times 10^{-7}$ per roentgen, which is about fifteen times the rate in *Drosophila*. This suggests that 30–40 per cent of human mutations might be due to high-energy events. Since these estimates are extremely uncertain, I still do not think it impossible, or even very improbable, that most human mutations may be so caused. This hypothesis gives an upper limit to the possible harmful effect of induced radioactivity. Even if, as I hope, this limit is too high by a factor of ten or even a hundred, it seems worth stating, if only because, while suggesting a more serious situation than some physicists have calculated, it decisively negates prophecies of wholesale racial degeneration resulting from experimental atomic explosions.

Imprinting in Animal Behaviour

A RECENT symposium on imprinting[1] focuses attention on a very important aspect of animal behaviour. Although Thorpe[2] and Verplank[3] have emphasized that imprinting should be considered in relation to other types of learning, one aspect which does not appear to have received much consideration is the question of the relevance of imprinting to ideas on the evolution of learning and of instinctive behaviour.

I would first like to direct attention to an anatomical parallel which may be helpful. In *Drosophila*, heat-shock at an appropriate stage results in the development of the cross-veinless phenotype.

Waddington[4] has shown that selection of those individuals which give the maximal response to the environmental heat stimulus builds up a genotype the reaction norm of which is gradually altered so that cross-veinlessness becomes more and more readily developed. Finally, a stage is reached where the environmental stimulus is no longer necessary, and the animals show the cross-veinless character without the necessity for heat treatment.

In the evolution of a fully innate behaviour pattern evoked by a releaser, it seems possible that a similar process may have occurred. It is difficult to imagine that the process could begin otherwise than with the making of an appropriate response, probably imperfectly performed and subject to trial and error, and with learning of a simple conditioning type involved in the determination of the situation in which the response is made. From this stage there will be rapid selection, on one hand for more perfect performance of the motor response, and on the other for the shortening of the conditioning period, provided the environmental stimulus (or some special part of the total stimulus situation) remains constant. As in the case of cross-veinless, this should result in the building up of a genotype giving the motor response in more and more perfect form with the learning period more and more curtailed. The final result will be the innate pattern evoked by its releaser. But may not imprinting represent a penultimate stage on this route, a stage in which the motor response has been perfected and the learning period has become vestigial but has not yet disappeared ?

If this interpretation is valid, then some curious facts receive a possible explanation. Thorpe[5] has pointed out that in birds the characteristic song of the species is sometimes innate, sometimes imprinted and sometimes fully learnt. Even closely related species may differ in this character in a manner which is at first sight puzzling. If, however, these actually represent stages in the evolution of the innate pattern which has not yet been fully attained in all species, then the situation is comprehensible.

This, however, cannot be the whole story. If we refer again to anatomical parallels, we see that in many cases an adaptive 'developmental response' is innate—the classical case is the callosities of the ostrich ; but in other cases the adaptive response remains a response to a necessary environmental stimulus—muscle hypertrophy with use and skin cornification in response to rubbing are the classical examples. In these latter cases it is easy to appreciate that the adaptive response to the stimulus is a more efficient device than a fully innate response would be. Full cornification of all skin areas potentially liable to rubbing might save the minor discomfort of a few blisters, but would detract greatly from tactile sensitivity and ability to do fine work ; and maximal development of all muscles at all times would be physiologically wasteful. It is therefore relevant to ask, in the case of imprinting, whether in some cases there may not be a selective reason for the retention of the vestigial learning period, that is, whether the imprinting situation may not be more advantageous than a fully innate response would be. I believe that this is true in 'olfactory conditioning' of insects to their animal or plant hosts, of the type described by Thorpe[6] in the case of *Nemeritis*. Here, so long as recognition of the host is imprinted, no genetical change in its chemical constitution will rid it of its insect parasite or predator. Imprinting automatically keeps pace with any such change, whereas in the case of an innate response to a specific chemical stimulus, any mutation giving rise to a changed odour would render the host immune to attack.

There are other cases in which there also appear to be reasons for the imprinting period being retained. Verplank[3] suggests that in species showing parental care imprinting should occur most frequently in those the young of which are active very shortly after birth or hatching. This, I believe, may be a sort of evolutionary concession to the imperfectly developed sensory faculties of the newly born or hatched young. Since they are active and must be protected, a following response is necessary ; but if their sensory faculties are as yet defective and the parent is at first little more than a moving object, then, perforce, the response must be to 'moving object'. At the same time, recognition of the parent must develop as rapidly as possible ; and the most effective solution is what is actually found—an innate following response to any moving object, followed by fairly rapid imprinting. If this is correct, then we should find not only the correlation of imprinting with early locomotion suggested by Verplank, but also that speed of imprinting should be correlated with the development of sensory discriminatory abilities.

Environmental Factors influencing Gonadotrophin Assay in the Rat

IT has hitherto been assumed that environmental factors play their part in establishing the final characteristics of a population predominantly as modifiers of development[1,2]. This is clearly so when the end-products of cellular activity, as expressed in relatively stable anatomical structures, are under examination. When, however, attention is directed to the potentialities of an organ or tissue by measuring the rate of cellular activity, as in the response of tissues to the action of drugs, the environment can be expected to play a more immediate part.

Studies of the influence of factors in the environment of the immature female rat receiving serum gonadotrophin have revealed that they take a major part in determining not only the sensitivity of the ovarian-weight response, but more especially the variability within the group.

The following is a description of the test and a tabulation of representative results : Two days following weaning at 21–26 days old, each immature female rat is injected subcutaneously with 50 international units of 'Antostab' serum gonadotrophin in 0·2 ml. of distilled water. A similar injection is given on the three subsequent days in the morning, making a total of 200 international units in four days. The rats are killed on the fifth day and the ovaries dissected and weighed (mgm.) fresh after blotting on filter paper. All the injections are made immediately after the operator's hands have been washed, as the presence of smells from fæces or disinfectant on the hand was found to depress the response.

Effect of Changes in Cage Conditions

12/group 4/cage
Litter mates together

Cage	Mean (mgm.)	Coefficient of variation (per cent)
Unchanged	122	13·4
Daily change	87	18·9
Litter mates distributed over treatments		
Unchanged	117	6·6
Daily change	80	14·0

Effect of Non-recurrent Changes in the Social Environment
(In this test the animals were redistributed each day in such a way that they did not encounter any of their litter mates during the rest of the test. Since this test involved a new cage for each rat that was placed with new cage mates, the cages of all the groups were changed each day)

16/group 4/cage
Litter mates together at start

No. of changes	Mean (mgm.)	Coefficient of variation (per cent)
0	99	8·3
4	111	17·9

Effect of the Number of Rats per Cage
(The size of cage was doubled for six and eight rats per cage in order to keep the area per rat roughly constant.)

No. in cage and date of test	Mean (mgm.)	No. in group	Coefficient of variation (per cent)
1 (25.2.55)	80	12	24·3
2	114	12	4·8
4	111	12	7·3
6 (13.5.55)	96	12	18·0
8 (18.5.55)	87	16	15·2
Repeat test			
1 (8.6.55)	160	12	30·6
2	212	12	5·7
4	231	12	8·5

Note that the response in the second test was nearly twice that in the first. This change in sensitivity is occasionally encountered and is usually termed 'seasonal variation'. On this occasion, however, the increased sensitivity lasted only a matter of a few weeks

Effect of Size of Cage

8/group 2/cage

	Mean (mgm.)	Coefficient of variation (per cent)
Large	135	12·1
Medium	151	6·4
Small	157	28·6
	8/group	8/cage
Large	145	8·9
Medium	159	8·9

The medium cage is twice the size of the small cage and the large cage is twice that of the medium. The dimensions of the small cage are 9 in. × 12 in. × 6 in. high.

The response of the rats to follicle-stimulating hormone was clearly modified by the environment in which the rat was placed during the test. It is thus necessary to consider the interaction between the genotype and the environment as taking place in two ways. On one hand, environmental influences will modify development and so bring about variability in responsiveness to drugs within a population. On the other, the environment will cause variation by differences in the responsiveness of different animals to the pattern of stimuli present during the period when the drug is acting. These two categories may well interact to some extent separately with the genetic background. Moreover, since the immediate effect of the environment on the action of drugs appears in large part to be a nervous response, the environmental contribution to variability arising out of influences affecting the behaviour of the animals may be more closely linked to the genetics of the nervous system than to other hereditary differences.

Environmental Factors affecting Hairiness in Mosquito Larvæ

Rosen and Rozeboom[1] have described a wide range of variation in larval hairiness in the *Aedes scutellaris* group of mosquitoes in Polynesia, and have shown that hairiness is conditioned by some environmental factor common in, but not restricted to, tree-holes. A similar situation has now been discovered in the related *Aedes albopictus* in Singapore; here, larvæ from tree-holes frequently have many of the body hairs longer, stouter and with more branches than in the normal form (Fig. 1). A colony established from hairy larvæ produced only normal larvæ in the laboratory, and the hairiness is clearly produced by some environmental factor. Rearing experiments showed that larvæ raised in the contents of some, but not all, tree-holes became hairy; siblings from the same batch of eggs, reared in tap water plus yeast, or in grass infusion, were normal. The related *Aedes aegypti* also gave hairy larvæ when reared in the appropriate medium, but *Culex fatigans* larvæ were not affected.

Since larvæ mature in five days in grass infusion, but may require up to fifteen days in tree-hole contents, it seemed possible that length of the growth period might affect hairiness. This was tested by rearing at different levels of nutrition; but no such effect could be detected. Also to be considered are the microflora and fauna of the tree-hole water, mainly crustaceans, rotifers, fungi and bacteria. However, cultures produced by inoculation of boiled grass infusion, when tested, gave no increase in hairiness. The living organisms, then, do not appear to play any direct part.

Rosen and Rozeboom[1] offer evidence that hairiness is associated with the presence of organic debris in the water; when this was removed by filtration, normal larvæ resulted. This has been tested for *A. albopictus*. Larvæ were first reared in supernatant fluid from a tree-hole culture, renewed daily; these proved to be as hairy as those from the original culture. Larvæ were then reared in tree-hole water filtered twice through Whatman's No. 1 paper; also, for comparison, in a water suspension of the debris, and in the original water. The two latter cultures gave all hairy larvæ; but those from the filtrate were also hairy, though to a reduced degree—specimens ranged from typically hairy down to almost normal. Finally, water, known to produce hairiness, was passed through a Seitz filter under sterile conditions, and two cultures were set up; in one, air-borne bacteria, etc., were allowed to accumulate, and the

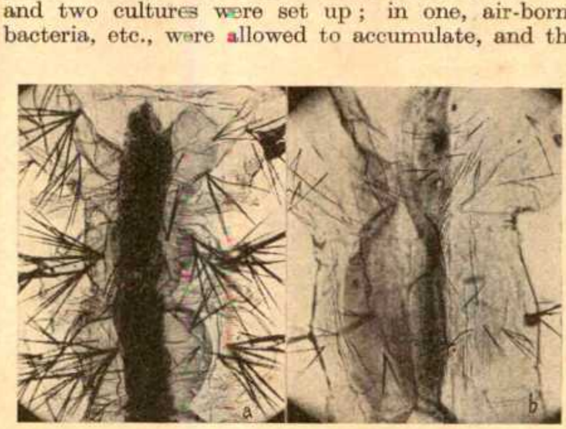

Fig. 1. *Aedes albopictus*, base of larval abdomen: (*a*) hairy larva; (*b*) normal larva

other was re-inoculated with bacterial film from the original culture. Both were almost colourless, as compared with the original deep brown colour, showing that much colloidal matter had been removed. Larvæ of *A. aegypti* were tested in these; growth was slow, and only a few reached maturity, but these showed no increase in hairiness when compared with controls.

These experiments, and those of Rosen and Rozeboom, suggest strongly that the factors producing hairiness reside in some non-living particle, commonly found in tree-hole water. In this case the particles appear to be much finer than was the case in Polynesia. In attempts to produce such particles in the laboratory, tests have been made of infusions of sawdust and suspensions of crude lignin, but none of these has caused any increase in hairiness of *A. albopictus* larvæ.

The nature of these particles is to be investigated further and the full results will be published in due course. Acknowledgments are due to Mr. Cheong Chee Hock for assistance with the photomicrographs, and to Dr. Lim Kok Ann for carrying out the filtration described above.

Distribution of Physiological Races of *Phytophthora infestans* (Mont.) de Bary in Northern Ireland

Early reports on the distribution of physiological races of *Phytophthora infestans* (Mont.) de Bary showed that specialized races occurred only in districts where resistant potato seedlings were raised and grown[1-3]. Furthermore, it was considered that the unspecialized race, later designated race 0, was the only one to cause disease in commercial potato crops.

More recent work, however, has shown race 4 in Holland[4], and a mixture of race 0 and race 4 in Canada[5], to be the 'common race'.

A further contribution to our knowledge of the distribution of the physiological races of *P. infestans* may now be made from a survey carried out in Northern Ireland. Diseased potato foliage was collected from all parts of the country in 1954 with the view of ascertaining the identity of the most widespread race(s). A further collection from a locality at which many potato varieties, including many *Solanum tuberosum* × *Solanum demissum* hybrids, were being grown was also made in order to obtain as many different physiological races of the fungus as possible. The isolates of the fungus were cultured on pea-meal agar at 15–18° C. and identified by the detached leaf technique, using the variety British Queen and Black's set of single-gene differentials as the differential host series.

From seventeen commercial varieties (all *S. tuberosum* derivatives), seventy-three isolates of the fungus were obtained. Of these, seventy were identified as race 4 and the remaining three as race 0. These latter occurred on the varieties Arran Victory, Ulster Supreme and British Queen.

A total of nineteen isolates was obtained from the hybrid varieties. Of these, six remained unidentified due to lack of pathogenicity, and from the reactions of the remainder race 1, race 2, race 4, races 1, 2, races 1, 4, and races 1, 2, 4 were identified.

It is evident that at least seven physiological races of *P. infestans* are present in Northern Ireland but only one, race 4, has a widespread distribution.

Rhizoctonia in Natural Grassland Soils

An investigation into various aspects of the microbiology of natural grassland soils is being carried out in these laboratories to serve as a guide in future studies on the microbiology of soils under introduced pasture grasses.

The native 'low tussock grasslands'[1] of New Zealand, with *Poa* and *Festuca* spp. dominant, cover approximately 7 million acres and occur mainly in the South Island. Areas are found from sea-level to 3,000 ft. and they provide extensive grazing for sheep. Three locations were chosen for sampling, one in the North Island on soil derived from volcanic ash (Waiouru) and two in the South Island, one on soil derived from sandstone (Bealey) and the other on soil derived from schist (Alexandra).

In a study of the mycology of these soils, the screened immersion-plate technique[2] and a plating method described by Warcup[3] were employed in parallel studies. Modified screens were employed in the former by constructing them with sides to form a shallow box. When assembled, the sides of the screens fitted closely over the sides of the boxes carrying the agar-coated plates in a manner similar to the fitting of Petri dish halves. 2 per cent distilled water agar was used, and the diameter of the screen apertures was reduced to ⅛ in. Isolations were made from ten sites in each location in the spring, summer and autumn seasons of 1953–54. A total number of 1,669 specimens of mycelium were isolated by the screened immersion plates, and, of these, 831 specimens exhibited features of hyphal morphology similar to those shown by strains of the fungus *Rhizoctonia solani* Kuhn[4].

The predominance of *Rhizoctonia* mycelium as shown by screened plates was a constant feature in the three locations, the fungus occurring in both top and subsoil. In contrast, mycelium of *Rhizoctonia* was not recorded on any occasion with the plating method, although a number of other fungi were isolated. The failure to obtain *Rhizoctonia* by this method may be associated with the difficulty of maintaining transfer cultures on potato dextrose and malt agars.

In the extensive literature pertaining to soil mycology studies, there are few references to the occurrence of *Rhizoctonia* in isolations[5]. The majority of references concerning this much-studied fungus deal with pathogenic activity, and the direct isolation of the organism from sources other than infected material is seldom recorded.

The remarkable occurrence of *Rhizoctonia* in screened plate isolations in contrast to its absence in soil plates led to the application of other techniques to confirm the presence of *Rhizoctonia* mycelium in these tussock grassland soils.

Rossi–Cholodny[6] slides were prepared from the Waiouru soil and on microscopical examination showed widespread occurrence of *Rhizoctonia* mycelium. Examples of the previously recorded[7] hyphal contact association between actinomycetes and soil fungi, including *Rhizoctonia*, were also observed.

Agar-soil films devised by Jones and Mollison[8] were prepared from the soil at Waiouru, and hyphæ exhibiting characteristics associated with *Rhizoctonia* were recorded.

Finally, blocks of soil were brought to the laboratory and broken open along natural fracture lines by hand and directly examined with the aid of the incident-light equipment of a Leitz 'Ortholux' microscope. Mycelium with features associated with *Rhizoctonia* were observed frequently (see Fig. 1). By freehand manipulation with a sterile needle under incident light, portions of such mycelium were removed to normal microscope slides and identification confirmed.

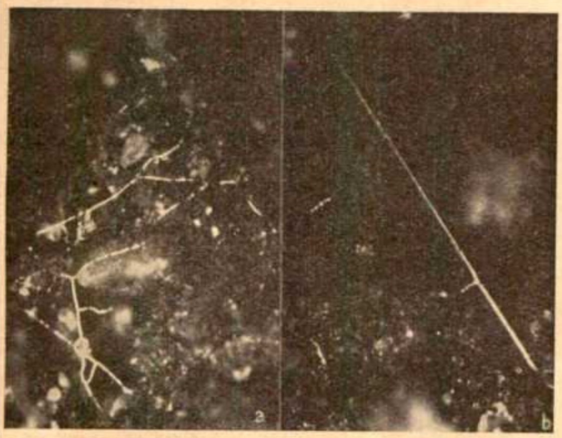

Fig. 1. *Rhizoctonia* hyphæ in natural grassland soil. Photographed by incident light with 35-mm. 'Alpha' reflex camera and extension tube. (*a*) × 75 ; (*b*) × 125 approximately

The results have shown that the soil plating technique was unable to give a true indication of the fungus flora of these soils, as there was no evidence to show the presence of *Rhizoctonia* as active and widely occurring mycelium.

The abundant occurrence of one of the Mycelia Sterilia in screened immersion plates is claimed to be strong evidence that this technique isolates fungus specimens in the mycelial state from soil.

Results will be published in full at a later date.

Mycelial Aggregation of Sand Soil under *Pinus radiata*

THE influence of soil micro-organisms upon the physical condition of soil has received some attention in recent years. Various workers[1] have shown that fungi and bacteria and their associated metabolic products are capable of affecting the structure of soils. Fungi act largely by the entangling effect of their hyphæ, and bacteria produce cementing and binding substances of a polysaccharide nature[2].

The present communication records the observation in the field of fungal mycelia occurring in quantity in soil, possibly associated with a measurable difference in structure.

During a survey of the sand soils of the Manawatu County, a difference was noted between Himatangi sand under manuka scrub (*Leptospermum* spp.) and this soil under *Pinus radiata*. Himatangi sand before afforestation was a weakly gleyed, yellow-brown sand, melanized by scrub, rushes and sedges. Under manuka the topsoil consists of seven inches of black, sandy soil with a weakly developed and very friable nutty structure (10–20 mm.). Under *P. radiata*, close to the bases of individual trees in a twenty-five year old plantation, the topsoil has a more fluffy appearance and a more strongly developed structure ; individual aggregates, although friable, tend to cling together and some pressure is needed to separate them.

Within the soil under *P. radiata* trees there is a visible, very extensively ramifying network of fungal hyphæ, associated with tufts of yellowish mycelium. The hyphæ occur in great abundance and invest sand particles and aggregates to such an extent that a degree of physical cohesion is imparted (see Fig. 1).

Three samples of Himatangi sand under manuka and three under *P. radiata* were taken from nearby sites and several physical measurements were made (see Table 1).

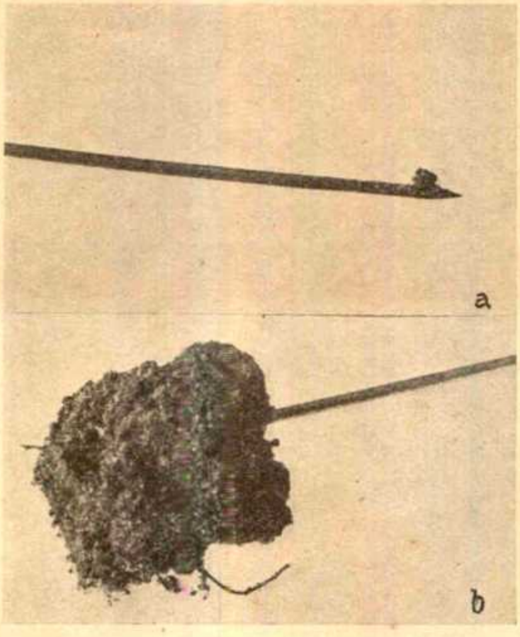

Fig. 1. Aggregation of sand soil by fungal hyphæ : (*a*) under *Leptospermum* spp., (*b*) under *P. radiata*. Approximately natural size

Table 1

	Under *P. radiata*	Under *Leptospermum* spp.
	Means and 95 per cent confidence levels	
Total porosity (per cent)	58·2 ± 2·9	58·1 ± 4·1
'Large pores' (per cent)	24·9 ± 7·8*	12·3 ± 10·5

* Significant difference at the 5 per cent level.

Total porosity per cent is defined as :

$$\frac{\text{Volume of air in undisturbed sample}}{\text{Total volume of undisturbed sample}} \times \frac{100}{1}$$

The percentage of 'large pores' was measured by saturating undisturbed samples with water and then draining at a tension of 50 cm. water ; it is expressed as :

$$\frac{\text{Volume of pores drained}}{\text{Total volume of undisturbed sample}} \times \frac{100}{1}$$

No difference in stability of soil aggregates between the two sets of samples could be determined by standard wet-sieving methods, because the aggregates from both sites disintegrated with these techniques. However, when transferring saturated samples it was noted that a certain amount of the samples fell away. This manipulation was standardized and samples were weighed before and after handling, and the 'ability of aggregates to cohere' is expressed as :

$$\frac{\text{Weight of sample after handling}}{\text{Weight of original sample}} \times \frac{100}{1}$$

The large difference in variances between the two sites makes it impossible to compare these results by a t test. However, there appears to be a relatively greater cohesion in aggregates in samples taken from under *P. radiata* ; for example,

Under *P. radiata*	Under *Leptospermum* spp.
98·9	93·3
98·9	95·6
98·7	89·2

As the total porosity of the two soils is not significantly different, it is possible that the increase in 'large pores' per cent and the probable increased cohesion in soil under *P. radiata* could be attributed to the entanglement of soil particles by extensive fungal mycelia.

Microscopical examination showed that the predominant hyphæ possessed abundant clamp connexions, indicating that the mycelia largely belonged to species of the Basidiomycete group. Sporophores of *Rhizopogon rubescens*, *Clathrus cibarius* and *Geastrum plicatum* were often collected and small agarics occasionally seen on the area. It is not known whether the mycelia are of one species or of a mixture of several species. The visible tufts of yellowish mycelium appeared to be loose strands of many hyphæ (see Fig. 2) extending between decomposing plant fragments, whereas the more generally occurring hyphæ ramified extensively about sand particles and small aggregates (see Fig. 3) and particularly about decomposing fine root fragments. (Figs. 2 and 3 were photographed by incident light with a 35-mm. 'Alpha' reflex camera and extension tubes.)

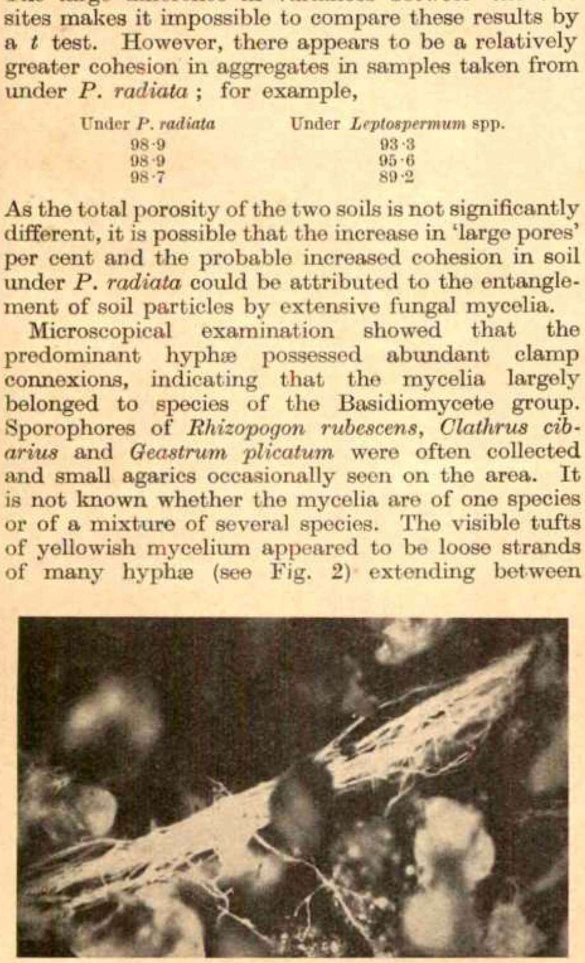

Fig. 2. Hyphæ forming a loose strand in sand soil under *P. radiata*. × 75 approximately

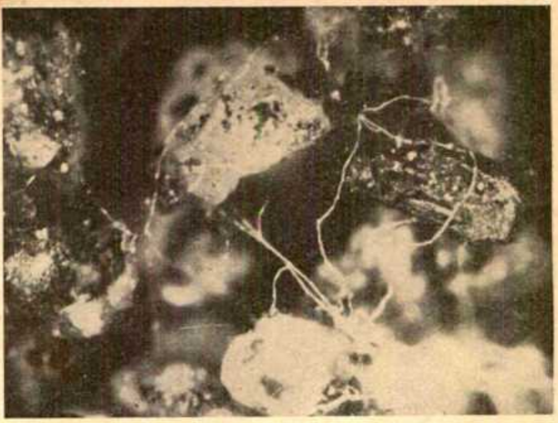

Fig. 3. Hyphæ investing sand grains in sand soil under *P. radiata*. × 160 approximately

Hyphæ were of four types : (*a*) yellowish, roughened-encrusted, septate hyphæ, 3–4 microns in diameter with clamp connexions ; (*b*) brown, very slightly roughened, septate hyphæ, 3–4 microns in diameter without clamp connexions ; (*c*) hyaline, roughened-encrusted, septate hyphæ, 2·0–2·5 microns in diameter with clamp connexions ; (*d*) yellowish, smooth, septate hyphæ, 3–4 microns in diameter with clamp connexions. Types (*a*) and (*b*) were associated with the strands of mycelium, whereas (*c*) and (*d*) occurred more generally within the soil.

The occurrence of Basidiomycete mycelia in such abundance in sand soil under *P. radiata*, sufficient, apparently, to produce a measurable difference in structure, appears worthy of record. Further observations are being carried out on this phenomenon and on grey 'bleached spots' occurring in this sand, which may be associated with the above condition.

A Gigantic *Holoptychius* from Dura Den

THE Upper Old Red Sandstone deposits of Dura Den in Fife are world-famous as a source of fossil fish, among which the dominant genus is the crossopterygian *Holoptychius*. Extensive collections are extant from excavations sponsored by the British Association in 1913 and from the work of earlier investigators.

A new fossiliferous stratum, some 35 ft. above the classical horizon, was found at Dura Den in 1954. From this there has just been recovered the central region of a *Holoptychius flemingi* very much larger than any individual yet recorded. Measurements suggest a fish from eight to nine feet in length and a foot in girth. The remarkable size of this specimen merits a mention of the discovery.

A Biological Factor inhibiting the Effect of Cortisone on Antibody Formation

PREVIOUS investigations in the adult white rat[1] have shown that intramuscular administration of cortisone can depress the hæmolysin response after a single intraperitoneal injection of sheep erythrocytes. The effect of cortisone is dependent on (1) the dose of antigen, (2) the dose of hormone, and (3) the time of administration of hormone (location in time in relation to the antigen injection). At the respective dose-levels (per 100 gm. weight) of 4 mgm. a day of cortisone and 2 ml. of a 0·03–0·3 per cent suspension of sheep erythrocytes the following time limits were found: a maximum effect was obtained when cortisone was given for three days, beginning two days before the antigen injection and ending with an injection on the day of antigen injection. The lack of significant effect of hormone injections after the day of antigen injection indicates that an early phase of the production of antibody is disturbed by the action of cortisone.

Of considerable interest in this connexion are investigations on the effect of total body irradiation on antibody formation (see footnote 2 for references). Several reports have indicated that a short initial period of the antibody production process is especially sensitive to damage produced by exposure to X-rays. There is thus a striking temporal similarity between the effects of cortisone and X-rays on antibody metabolism.

Investigations by Jacobson and his associates[3] on rabbits and rats have demonstrated that the depressing effect of X-rays on antibody formation is largely abolished by lead shielding of the spleen during irradiation. In the following experiments it has been shown that spleen or thymus cells from intact donors have a similar protective effect on rats treated with cortisone.

The test effect was the primary hæmolysin response in the rat and the experimental conditions those outlined in the first paragraph. Cortisone was given for six days, beginning four days before the antigen injection. The animals were bled on the fifth and seventh day after the antigen injection. The hæmolysin titre of serum was determined by a conventional method (titration by double dilution steps, guinea pig complement, sheep cells, incubation at 37° C., centrifugation and reading against a scale). The cell suspensions were prepared as follows: spleens or thymus glands were taken from adult rats weighing 200 gm. and 300 gm. The organs were finely minced, passed through a metal screen and suspended in a mixture of saline (2 parts) and Tyrode solution (1 part). Larger fragments, connective tissue, etc., were eliminated by filtration through sterile gauze. The cells were spun down at 1,500 r.p.m. for 10 min. and then resuspended in saline–Tyrode. The volume of the suspension was adjusted to contain cells from half a spleen (or a corresponding amount of thymus) in 3 ml., which constituted the standard dose. This dose, which was injected intraperitoneally, contained between 3 × 10^8 and 7·5 × 10^8 nucleated cells. Most of these cells appeared to be in a good condition when examined in a phase-contrast microscope.

Table 1. EFFECT OF INTRAPERITONEAL INJECTIONS (DURING 4 DAYS) OF HOMOLOGOUS SPLEEN CELLS FROM INTACT DONORS ON ANTIBODY RESPONSE IN RATS TREATED WITH CORTISONE
Immunization: single intraperitoneal injection of sheep erythrocytes (on day 0). Antibody: hæmolysins measured on the fifth day (day 0 + 5) after the antigen injection and expressed as negative logarithm of the titre

Group	Treatment	No of rats	Hæmolysin titre		P
			Mean ± ε (mean)	Difference ± ε (diff.)*	
I	Suspending agent of hormone	5	3·44 ± 0·44†	2·30 ± 0·64	< 0·01
II	Susp ag. horm. + spleen cells‡	5	4·38 ± 0·50†		
III	Cortisone + spleen cells‡	5	4·24 ± 0·40	3·10 ± 0·62	< 0·01
IV	Cortisone = controls	5	1·14 ± 0·47	—	

* Difference between the group mean and the mean of the control group (IV).
† Difference between the means of group II and I = 0·94 ± 0·57 ($P > 0·1$).
‡ Spleen cells were given from day 0 until day + 3.

In the first experiment (Table 1) two injections of spleen cells were given daily for four days beginning 5 hr. after the antigen injection. Cortisone alone produced a significant reduction of the hæmolysin response. When spleen cells were administered to animals treated with hormone, the mean antibody titre was significantly enhanced and there was no depression of the antibody response. In other experiments (Table 2) it has been shown that the same result can be produced by only one injection of the same dose of spleen cells if it is given on the day of antigen injection (hitherto injected 2 hr. after the antigen). Thymus cells seem to have the same effect (Table 2). Injections of spleen cells on the first, second and third day after the day of antigen injection have not been significantly effective. As shown in Table 2, the administration of spleen cells one day (22 hr.) before the antigen injection did not protect antibody production against cortisone.

In two experiments it has been shown that disintegration of spleen cells (grinding in a homogenizer at high speed) destroys their protective effect on antibody formation. Subcutaneous administration of intact cells gave no demonstrable enhancement of antibody response in animals treated with hormone.

Table 2. EFFECT ON ANTIBODY RESPONSE IN CORTISONE-TREATED RATS OF A SINGLE INTRAPERITONEAL INJECTION OF HOMOLOGOUS SPLEEN CELLS ON THE DAY BEFORE (DAY – 1) OR THE DAY OF (DAY 0) ANTIGEN INJECTION, OR (2) HOMOLOGOUS THYMUS CELLS ON DAY 0. Immunization and antibody determination as in Table 1, with the exception that hæmolysins were measured on day + 7.

Group	Treatment	No. of rats	Hæmolysin titre		P
			Mean ± ε (mean)	Difference ± ε (diff.)*	
I	None	9	1·89 ± 0·36	1·50 ± 0·41	< 0·01
II	Cortisone + spleen cells day – 1	8	0·35 ± 0·24	–0·04 ± 0·31	—
III	Cortisone + spleen cells day 0	7	3·43 ± 0·44	3·04 ± 0·45	< 0·001
IV	Cortisone + thymus cells day 0	9	2·03 ± 0·51	1·64 ± 0·55	< 0·01
V	Cortisone = controls	9	0·39 ± 0·20	—	

* Difference between the group mean and the mean of the control group (V).

The present results suggest that the spleen and thymus cells contain or, more probably, produce a factor, or have a cellular function, essential for some initial, cortisone-sensitive phase of the antibody production process.

Inhibition of Influenza Virus Hæmagglutination by a Brain Lipid Fraction

THERE exists a rather ill-defined group of complex lipids that could be subsumed under the name of 'mucolipids'. These substances, while possessing constituents commonly considered characteristic of the cerebrosides, share some properties with the mucoproteins. Thus, they are soluble in water and include amino-sugars and a nitrogen-containing acid which gives rise to a violet colour with Bial's reagent and to a colour reaction with *p*-dimethylaminobenzaldehyde without previous treatment with alkali. We shall here refer to the substance yielding a direct Ehrlich reaction as 'direct chromogen', since we are not in a position to decide whether we are dealing with sialic acid[1], which was first isolated from submaxillary gland mucin[2], or with neuraminic acid[3] found in a group of lipids later designated as gangliosides[4]; nor indeed whether these two compounds differ.

Lipids of this type appear to have been encountered frequently in the older literature; but two fractions have been investigated in some detail, namely, the gangliosides occurring in nervous and other tissues[4,5], and strandin, a high-molecular lipid complex from brain[6]. The latter, to be exact, is stated to contain less than 1·5 per cent of neuraminic acid; but there can be little doubt that, as we shall show below, by a procedure similar to one of the methods used in the isolation of strandin (the 'partition-dialysis method'[6]), a lipid fraction can be obtained that contains about 20 per cent of 'direct chromogen' (compare also Chatagnon and Chatagnon[7]).

We have found that the lipid material isolated from the grey matter of ox brain by partition-dialysis, though having much in common with the gangliosides, can be distinguished from the latter: it possesses, in contrast to the ganglioside preparations tested, a strong inhibiting action on the agglutination of chicken erythrocytes by influenza virus. The isolation of the inhibiting lipid preparation was carried out at low temperature. Portions of freshly obtained grey matter were treated with 10 parts (v/w) of chloroform–methanol (2 : 1, v/v) in a high-speed mincer for 2 min.; the filtrate was subjected to dialysis in large 'Cellophane' bags against frequent changes of a 30-fold volume of distilled water for three days; the aqueous portion of the dialysis residue was reduced to about 0·7 per cent of its initial volume by rapid evaporation *in vacuo* at 30°; the concentrated solution was, after repeated dialysis as before, clarified by centrifugation (2,100 *g*, 30 min.) and freed of water by evaporation in the frozen state in a vacuum.

A typical preparation (prep. *IL*-1) accounted for about 0·3 per cent of the starting material and had nitrogen 3·9 per cent, phosphorus 0·7 per cent and a low iodine value (about 17). It contained 23 per cent hexose, identified as galactose, 4·5 per cent amino-sugar, identified as chondrosamine, and 20 per cent 'direct chromogen'. The absorption spectra resulting from the reaction of the chromogen with *p*-dimethylaminobenzaldehyde, diphenylamine, and Bial's reagent closely corresponded to those reported for sialic acid[8]. The study of other components is not yet completed; for example, a fatty-acid fraction and a number of amino-acids, of which several have been identified tentatively and which appear to constitute a polypeptide moiety yielding a weak biuret reaction and a single dinitrophenyl derivative.

Influenza virus (type *A*, *PR*8 strain), in the form of infective chorioallantoic fluid, was heated to 56° for 30 min. for use as 'indicator' virus in tests for inhibition of hæmagglutination. Under the conditions of assay, five hæmagglutinating units were regularly inhibited by a minimum of 10–20 μgm. of preparation *IL*-1, and in concurrent assays by a minimum of 2–5 μgm. of urinary mucoprotein[9].

For use in enzymic experiments, concentrated influenza virus (*PR*8) was prepared by centrifugation of fully infective chorioallantoic fluid (25,000 *g*, 1 hr.). The hæmagglutinating titre of the sedimented virus, taken up in a small volume of buffered saline (nine parts of 0·9 per cent sodium chloride, one part of 0·01 *M* phosphate buffer, *p*H 7·2) was twenty to thirty times that of the original chorioallantoic fluid. The lipid preparation, after incubation with concentrated active virus at 37° for 22 hr., lost completely its capacity to inhibit 'indicator' virus hæmagglutination, and 24·5 per cent of the 'direct chromogen' was split off in a dialysable form. Lipid treated with concentrated active virus at 4° for 22 hr., however, lost virtually none of its inhibitory potency, and no dialysable split products were found. Incubation with the receptor-destroying enzyme of *Vibrio cholerae* (30°, 24 hr.) also brought about complete inactivation and removed 39 per cent of the 'direct chromogen'. The power to inhibit virus hæmagglutination was also abolished by treatment with crystalline trypsin.

The success of further purification of the lipid material depended upon the procedures employed. When the separation by 'partition-dialysis'[6] was again applied to the isolated preparation, 64 per cent of the starting material was recovered as a fraction of undiminished inhibitory activity, containing 21 per cent of 'direct chromogen', and soluble in water, chloroform–methanol, moist benzene, and methanol. Procedures in which glacial acetic acid or pyridine were employed resulted in inactivation, though refluxing for 1 hr. in boiling chloroform–methanol or heating at 37° for 24 hr. in neutral aqueous solution did not affect the activity materially.

Two ganglioside preparations were also examined and proved completely inactive as inhibitors of hæmagglutination; they had been isolated, respectively, from the brain of a case of Tay-Sachs idiocy and from ox brain. The first-mentioned preparation also underwent 'partition-dialysis', as did the active lipid fraction *IL*-1 discussed before; it contained 32 per cent galactose, 5·4 per cent chondrosamine (as the hydrochloride), and 24 per cent of 'direct chromogen'. No amino-acids could be found in paper chromatograms of an acid hydrolysate. The receptor-destroying enzyme of *V. cholerae* attacked this lipid to a slight degree, effecting the detachment of 7 per cent of the total chromogen.

The presence of the 'direct chromogen' clearly is not the only requisite for inhibiting activity[10]. One gains the impression that the lipids discussed here may belong to a series of substances of increasing complexity and molecular size, leading from the monomeric cerebrosides to the gangliosides and then to mucolipids in which the presence of a polypeptide moiety is necessary for the inhibitory activity to become noticeable.

This work, some aspects of which will form the subject of a detailed communication, has been supported by the Life Insurance Medical Research Fund and the Office of the Surgeon General, Department of the Army, Washington, D.C. One of us (A. R.) held a predoctoral research fellowship of the United States Public Health Service. We are grateful to Dr. R. H. Barnes, of Sharp and Dohme, Inc., for the receptor-destroying enzyme.

Levels of Thyroid and Thyrotrophic Hormones in the Blood of Rats at Various Stages of the Œstrous Cycle

A COMPARISON was made between the levels of thyroid and thyrotrophic hormones in the blood of female albino rats during the four stages of the œstrous cycle. The procedure used was that adopted by D'Angello and Gordon[1], namely, 'the stasis tadpole method'. Serum was obtained from the blood of the rats, which were divided into four groups of five or six each according to the vaginal smear reading. These groups were of pro-œstrous, œstrous, metœstrous and diœstrous rats. The tadpoles were divided into five groups, one of which was the untreated control. The others were injected with seven injections of 0·01 ml. of serum obtained from the four groups of rats on alternate days. Twenty-four hours after the last injection the tadpoles were killed with chloroform, fixed in susa and stored in 80 per cent alcohol. Their hindlimbs were then measured with a micrometer; this was used as a criterion of thyroid hormone activity. The height of the epithelial cells of the thyroids of tadpoles was used as an indication of the level of thyrotrophic hormone in the blood of the different groups of rats. The results are shown in Table 1.

Table 1. THYROID AND THYROTROPHIC HORMONE-LEVELS IN THE BLOOD OF RATS AT THE STAGES OF THE ŒSTROUS CYCLE

Phase of cycle	No. of tadpoles	Mean increase of hindlimb above control (mm.)	Mean increase of height of epithelial cells above control
Pro-œstrus	17	1·02 ± 0·12*	0·69 ± 0·14*
Œstrus	13	1·58† ± 0·11	1·89† ± 0·15
Metœstrus	15	1·07 ± 0·08	0·64 ± 0·07
Diœstrus	22	0·84 ± 0·06	0·66 ± 0·07

* Standard error. † Significantly higher than other groups.

It appears clearly that thyroid activity increases during the œstrus phase when compared with the other three stages of the cycle. The rate of metamorphosis of the tadpoles injected with the serum obtained from this group of rats was the greatest. The increase of hindlimb above the control was 1·58 ± 0·11 mm. The rate of metamorphosis was at its lowest in the tadpoles injected with the serum obtained from diœstrous rats.

The level of thyrotrophic hormone in the blood of these animals parallels closely the state of the thyroid. Thyrotrophic hormone was found to be produced at its highest level during œstrus. These findings agree with previous observations which indicated that the uptake of iodine-131 by rat thyroids is at its highest during œstrus[2], and that the level of thyrotrophic hormone in the rabbit is higher during œstrus than during pseudopregnancy[3].

Amino-Acid Metabolism of *Nicotiana* Leaves after Removal from Plant

VICKERY *et al.*[1] have shown that after removal from the plant, *Nicotiana* leaves show a marked increase in the total soluble nitrogen (ammonia, amide and amino-nitrogen) whereas the insoluble protein nitrogen decreases. An attempt has been made in the present work to study, in detail, the amino-acid metabolism in such leaves using the technique of horizontal migration paper chromatography[2].

The free amino-acids originally present in the leaves, at 0 hr., show interesting variations after plucking. Though the content of tyrosine (R_F 0·66) does not show any notable increase, alanine (R_F 0·59) and glutamic acid (R_F 0·52) increase up to 120 hr. in the dark, after which they show a marked decrease. In light alternated with twelve hours of darkness, alanine and glutamic acid go on increasing until 144 hr., after which they show a slight decrease at 168 hr. Proline (R_F 0·63) shows interesting variations under conditions of both light and dark. Proline starts disappearing from the detached leaves when the latter are kept in the dark and becomes untraceable at 144 hr.; but in light alternated with darkness, it persists even up to 168 hr. without decreasing.

The content of aspartic acid (R_F 0·47) shows marked variations with time after removal from plant. It increases considerably during the first 72 hr. in the dark, after which it starts decreasing, reaching its minimum at 192 hr. It is important to note that in light (alternated with 12 hr. of darkness) the content of aspartic acid continues to increase, even up to 168 hr. The content of histidine–lysine (R_F 0·36) in the plucked leaf increases progressively in light and continuous dark even up to 168 hr. In the later stages, due to excessive formation of asparagine, the histidine–lysine band becomes superimposed by the thick asparagine band to form an asparagine–histidine–lysine complex. Asparagine (R_F 0·37) makes its appearance in the free state at 48 hr. after plucking and continues to accumulate up to at least 192 hr.

Apart from the changes in the various free amino-acids originally present in the leaves, other amino-acids also appear. Phenylalanine (R_F 0·83), and valine and methionine (R_F 0·76), which cannot be traced at 0 hr., make their appearance only 48 hr. after plucking and in the dark. They increase up to 120 hr., when they show the maximum depth of the bands. At 144 hr. and onwards valine–methionine is absent, but phenylalanine persists up to 192 hr. In light alternated with twelve hours of darkness, at 48 hr. after plucking, only valine and methionine appear, while phenylalanine appears only at 72 hr. Their content then increases up to 144 hr. in light, after which they are slightly reduced. It is to be noted that valine–methionine is not altogether lost even up to 168 hr. after plucking the leaves and in the light.

Multiple development of the chromatograms has shown that in light (alternated with 12 hr. of darkness), a new band, of R_F 0·51 lower than aspartic acid and higher than asparagine, is formed just after 48 hr. after plucking and goes on increasing up to 168 hr. This band is absent in the leaves kept in the dark. Multiple development of the chromatogram separates the lower bands, but it results in the formation of a phenylalanine–valine–methionine complex at the top as a thick broad band.

The possibility exists that the new range of free amino-acids are formed as a result of hydrolysis of insoluble leaf protein. The decrease with time in the amount of free amino-acids in leaves after removal from the plant suggests these are probably being used up in respiration. The persistence of proline in the light and the appearance of the new band suggest that some light-reacting systems are also involved in the metabolism of plucked *Nicotiana* leaves.

We thank Sri K. S. Bilgrami, Govindjee and T. Rajarao for their help during this investigation.

Nuclear and Cytoplasmic Volumes in the Hepatic Cells of the Fœtal Sheep

In an investigation of the development of the individual hepatic cell in the fœtal sheep, a new method was used to measure the volume of the nucleus and cytoplasm at different stages of development.

Material was fixed in Rossman's fluid (9 parts of a saturated alcoholic solution of picric acid to 1 part of 10 per cent neutral formalin), embedded in paraffin, sectioned at 5μ, and stained with hæmatoxylin and eosin. Measurements of the apparent length and breadth of twenty nuclei were made on each section. Nuclei were chosen at random, but measurements were made only on those the greatest diameters of which lay within the section as seen by focusing up and down. From these measurements the nuclear volume was calculated, making the assumption that the nucleus was in the form of a prolate spheroid with greatest diameter in the plane of the section and not at right angles to it. This method may involve a slight under-estimate of the nuclear volume in rare cases (in fact the greatest diameter usually lies in the plane of the section at right angles to the direction of 'section compression'), but it is unlikely to affect significantly the averages for each section. The mean nucleo-cytoplasmic ratio was then measured by the method of Chalkley[1]. Four series of observations each containing twenty-five 'hits' on nuclei were made for each liver, the average of the four values of the ratio so obtained was taken and the standard error of the mean used as an index of the error of the estimate. From the values of nuclear volume and nucleo-cytoplasmic ratio thus obtained, the cytoplasmic volume and the total cell volume were calculated.

The results of the measurements so far made are shown in Table 1. Although they provide no statistically significant evidence of change in the nuclear, cytoplasmic or total cell volumes between the 29-mm. stage and term, there is a suggestion that the nuclear volume may diminish slightly and the cytoplasmic volume increase; and this is supported by the fact that there is a statistically significant increase in the nucleo-cytoplasmic ratio over the same period. The positive regression coefficient is significantly different from zero ($0·05 > P > 0·025$). The results for the 22-mm. and 26-mm. fœtuses further suggest that prior to the 29-mm. stage the cytoplasmic volume and thus the nucleo-cytoplasmic ratio are increasing rapidly.

This apparent turning point at the 29-mm. stage may be correlated with the fact that histochemical investigation shows that glycogen first appears in the sheep fœtal liver at that time. As demonstrated in the chick[2], the appearance of glycogen coincides with "the loss of enzymatic activity necessary for the respiratory catabolism of glucose" and thus marks an important step in the development of the hepatic cell. It may well therefore be associated with a

Table 1

Synthesis of Long-Chain Fats by Bacteria isolated from Human Fæces

WE have recently isolated an organism from the stool of an adult human subject that is capable of synthesizing significant quantities of fatty material, which become visible on the surface, from a fat-free medium. The fat is neutral in character, liberating fatty acids on hydrolysis, and can be removed from the surface by dissolving it in ether. It is colourless and melts below body temperature. Some of its properties are shown in Table 1. Relatively little fat is present in the medium and organisms, and has not so far been investigated.

Table 1

Saponification value	190	Reichert value	42·1
Acid equivalent	294	Free fatty acids (as oleic)	0·27 per cent
Iodine value	49·5	Phospholipid (as lecithin)	0·7 per cent

The fat was prepared by inoculating a fat-free glucose peptone medium and allowing the fat to accumulate on the surface. The organisms were Gram-positive, and were observed in short chains and pairs. The organisms do not retain sudan black, but the fat produced in the medium stains readily with 50 per cent sudan black or sudan IV. (The organisms appear to resemble *Streptococcus faecalis.*) The growth of bacteria and the synthesis of fat are stimulated by the presence of folic acid as shown in Fig. 1.

These organisms were obtained from a patient with steatorrhœa under treatment with folic acid, and from the amounts obtained under these *in vitro* conditions, namely, 200 mgm. in four days in 10 ml. of medium, it would appear that fat synthesis of this type might make a significant contribution to fæcal fat. This possibility is being studied in other patients, and at the same time the properties of the fat and the factors affecting the quantity of fat formed are being more fully investigated.

Amino-Acid Patterns of Urine and Blood Plasma in a Cystinuric Labrador Dog

IT was shown by Lassaigne more than 130 years ago that cystine calculi may occur in the urinary tract of dogs. Canine cystinuria has since been recognized widely. Thus, more recently, 3 per cent of urinary calculi removed surgically from dogs in Holland and in Denmark[1] were composed of cystine, and 18 per cent in England[2], where White found them to be the commonest type (55 per cent of cases) causing urethral impaction. Canine cystinuria, with or without calculus formation, is said to be common also in France. Cystine calculi have been recorded from many breeds of dogs[2-4], but not hitherto from the Labrador. Furthermore, no study of the amino-acid patterns of the urine and plasma has previously been described; and hence it was not known if canine cystinuria is etiologically analogous with human cystinuria. If it were so, the usefulness of the cystinuric dog as a model for investigation of the human condition would be enhanced.

The subject of this communication is a male Labrador which first developed acute urinary retention in June 1951 when seven years old. Numerous small vesical calculi, and some impacted in the urethra near the penile bone, were removed surgically. A similar attack followed in November 1952, and also required urgent surgery. The animal was then placed on a reduced protein diet, and daily potassium citrate to alkalinize the urine; but, in spite of this, another crisis requiring surgical intervention occurred in October 1954.

Dent and Rose[5], in a study of fifteen cases of human cystinuria by means of two-dimensional paper chromatography, found that excessive urinary excretion of lysine invariably accompanied cystine, and that abnormal excretions of arginine and ornithine varied. The opportunity was therefore taken, after the second attack in this dog, of determining whether or not the amino-acid patterns in the urine and the plasma differed from those in human cystinuria.

One specimen of urine was obtained from the dog in November 1954, and a second specimen five weeks later. A sample of plasma was obtained with the second specimen of urine. Both specimens of urine gave strongly positive reactions for cystine with the sodium cyanide/nitroprusside test, and the typical cystine crystals were observed in the deposits after centrifuging.

The plasma was deproteinized, and the resultant liquid and the two specimens of urine desalted, oxidized and chromatographed by methods outlined by Dent[6]. 500 μl. of deproteinized and desalted plasma, and amounts of desalted urine corresponding to 250 μgm. of total nitrogen (Kjeldahl), were spotted on to 60-cm. squares of Whatman No. 4 paper, and were run in phenol saturated with water, followed by collidine–lutidine. The final positions of the amino-acids were revealed by spraying with a solution of 0·1 per cent ninhydrin in butanol, and examining after 24 hr. at room temperature.

Unidimensional chromatograms on Whatman No. 1 paper were run in butanol/acetic acid/water (4 : 1 : 5) using amounts of urine equivalent to 250 and 500 μgm. of nitrogen. No ornithine was detected after treatment with vanillin followed by alcoholic potash and heating. Histidine was detected in both specimens of urine by repeating the unidimensional runs in collidine–lutidine, and spraying with Pauly reagent.

In the first specimen of urine, cystine and lysine predominate, superimposed on a pattern consisting of glycine and taurine with traces of alanine, glutamine, serine, glutamic acid and methyl histidine. Traces of leucine and/or *iso*leucine and aspartic acid were obtained in the first specimen only, whereas threonine (confirmed by running with an authentic specimen) and β-alanine and/or citrulline were detected in both specimens of urine. Arginine was not detected in abnormal quantities.

In contrast to the affected dog, chromatography of a catheter specimen of urine obtained as a control from a healthy Labrador bitch nine months old revealed only a trace of cystine and no lysine. The amino-acid pattern consisted of glycine and taurine, with traces of alanine, glutamine, serine, methyl histidine and glutamic acid. The nitroprusside test for cystine was negative, and no cystine crystals were detected in the deposit after centrifuging the urine.

The amino-acid pattern of the plasma from the affected dog shows a small spot due to cystine (in contrast with the large spot found in the urine), supporting the view that we are dealing here, as in the human form of the disease, with a defect of tubular reabsorption of cystine from the glomerular ultrafiltrate. A similar mechanism would also account for the presence of lysine and threonine in the urine, since neither of these amino-acids was detected in the urine of the control animal.

The amino-acid pattern of the urine from this cystinuric dog is therefore, apart from threonine, identical with that found in cases of human cystinuria, while the finding of a low plasma-cystine points to a similar etiology.

Our thanks are due to Dr. Leon Duckett, who performed the surgery. One of us (C. W. C.) wishes to thank the Nuffield Foundation for a grant.

Formation of Calcium Superoxide

In connexion with an investigation on the formation and structure of certain alkaline-earth peroxides and superoxides, the dehydration of the compound $CaO_2.8H_2O$ has been studied. It has been proved that drying this hydrate with phosphorus pentoxide at room temperature will not yield pure CaO_2, but a substance with the following approximate composition: $Ca^{2+}(O_2^{2-})_{0\cdot87}(O_2^{-})_{0\cdot05}(O^{2-})_{0\cdot11}(H_2O)_{0\cdot10}$

The presence of superoxide ion (O_2^-) has been established by means of both chemical methods and by measuring the magnetic susceptibility.

The composition of this substance indicates that the dehydration is associated with a disproportionation of the following kind:

$$O_2^{2-} = (1-y)\,O_2^{2-} + \tfrac{2}{3}y\,O_2^{-} + \tfrac{2}{3}y\,O^{2-}$$

where y represents the degree to which the peroxide ions (O_2^{2-}) have been disproportionated.

Since the substance is hydrous, it is probable that the oxide ion exists as a hydroxide ion. Warming the dehydration product leads to an increase in the y-value, which, in the temperature interval 100–250° C., approaches 0·5. Heating to higher temperatures will cause decomposition.

X-ray photographs of the preparations have been taken using the Guinier method. In all cases the photographs exhibit only one phase with tetragona symmetry. The a-axis is constant, but the c-axis increases slightly with increasing y. The following values have been obtained: $a = 5\cdot03$ A.; $c = 5\cdot95$–$5\cdot97$ A.

Intensity calculations and density determinations indicate that the phase concerned has a variable composition. It can be described as a compound CaO_2 with a CaC_2-structure where some of the O_2^{2-}-ions (peroxide ions) in statistical distribution are substituted by O_2^--ions (superoxide ions) O^{2-}-ions, and OH^--ions. Some of the Ca^{2+}-ions are also substituted by O^{2-}-ions.

The results obtained thus indicate that the composition of the phase can be described by the formula

$$6(1-y)CaO_2\cdot 2yCa(O_2)_2\cdot 2yCaO\cdot 2yCa(OH)_2$$

where y ranges from $\sim 0\cdot1$ to $0\cdot5$.

This formula seems to be valid in all cases, where any warming has taken place of the product dehydrated at room temperature. Preparations obtained by dehydration at room temperature only are more hydrous than those which correspond to the general formula mentioned above.

If, on the other hand, the dehydration o $CaO_2.8H_2O$ is carried out directly at a temperature greater than 40° C., a phase is obtained the structure of which seems to be a superlattice of the tetragona phase mentioned above.

These investigations, which also include corresponding compounds with other cations as well as peroxide hydrates, will be described in detail in a forthcoming publication.

Homogeneous and Heterogeneous Graphitization of Carbon

It is well known that, on heating to temperatures between 1,700° and 3,000° C., some carbons show a continuous and homogeneous development of the three-dimensional structure of graphite, whereas in others the structure does not develop beyond the stage of small regions of 'turbostratic'[1] order. It has been shown[2] that graphitization is impeded when there is strong cross-linking between the small ordered regions (which are formed in all carbons at low temperatures), and also when there is random orientation between neighbouring ordered regions. Of these two factors, the latter is the more fundamental. At sufficiently high temperatures, cross-linking is always destroyed[2]; but, where random orientation exists, no homogeneous graphitization occurs.

In most non-graphitizing carbons, however, a small quantity of highly graphitic carbon is formed, as a separate phase, at some temperature above 2,000° C. This phenomenon has been interpreted in the following way[2]. When a carbon in which the ordered regions are strongly cross-linked in three dimensions is heated to high temperatures, great internal stresses develop; the system of cross-linking imposes a low overall thermal expansion, whereas the expansion coefficient of the ordered regions must be at least as great as that of graphite. This results in local breakdown of the cross-linking, followed by a corresponding local crystallization of the carbon under pressure, the process continuing until the internal stresses have been relieved to such an extent that no further breakdown of the cross-linking occurs.

Thus, we see that, although cross-linking prevents the homogeneous development of a graphitic structure, it promotes the heterogeneous formation of a small quantity of highly graphitic carbon in non-graphitizing carbons.

The above observations provide a possible explanation of some results obtained in an investigation of the influence of the oxidation of a coal on the graphitization of a coke prepared from it.

A coking coal which normally yielded graphitizing carbons was oxidized in air at 110° for periods up to twenty days. Samples withdrawn after different periods of oxidation were then heated at 2,700° C. It was found that short periods of oxidation of the coal (up to about five days) decreased the graphitization of the carbon. After longer periods, however, the graphitization again increased, but it now occurred heterogeneously instead of homogeneously; the X-ray diffraction patterns of the carbons showed clearly the presence of a mixture of highly graphitized and non-graphitized material (cf. ref. 2) rather than a single, partially graphitized phase[3].

These results suggest that mild oxidation of a coal leads to cross-linking which inhibits crystallite growth in the carbon, whereas in carbon formed from strongly oxidized coals the system of cross-linking is so strong that heterogeneous graphitization is promoted.

This interpretation was confirmed by a similar series of measurements made on a non-graphitizing coal oxidized in air at 110° C. for periods up to sixty days, and afterwards heated to 2,700° C. Both the raw coal and the coal oxidized for four days yielded carbons which showed neither homogeneous nor heterogeneous graphitization. A trace of heterogeneously formed graphitic carbon was first observed in the sample oxidized for fifteen days. Longer periods of oxidation resulted in the heterogeneous formation of larger quantities of graphitic carbon, the proportion reaching 9 per cent after sixty days of oxidation. Thus in this case, again, the strengthening of cross-linking brought about by oxidation increased the heterogeneous formation of graphitic carbon.

It therefore appears that graphitization can occur by two quite distinct processes. Homogeneous graphitization occurs in carbons in which neighbouring ordered regions lie in near-parallel orientation, and in which cross-linking is weak[2]. Heterogeneous graphitization results when cross-linking is so strong that, when it starts to break down at high temperatures, localized forced crystallization under pressure occurs.

Since heterogeneous graphitization involves the breakdown of cross-linking, it sets in at a higher temperature than homogeneous graphitization. The graphitic product, however, is more highly graphitized than a product of homogeneous graphitization at the same temperature, since it is crystallized under pressure.

The experiments described above were carried out during 1950 at the Laboratoire Central des Services Chimiques de l'État, 12 quai Henri IV, Paris. I am indebted to M. J. Méring for many helpful discussions.

Diffusion of Interlayer Water in Vermiculite

A convenient optical method for studying the diffusion of water molecules in vermiculite is outlined below. The effect has similarities to that employed by Tiselius[1] in his studies of diffusion in the zeolites; but, in this instance, it can be observed in reflected or transmitted light and is not a birefringence effect. Although magnesium vermiculite is referred to particularly, vermiculites saturated with cations other than magnesium behave in a similar (although not identical) manner.

When a flake of magnesium vermiculite, which has been partially dehydrated to the phase containing single sheets of interlayer water molecules (d_{001} = 11·59 A.), is allowed to become rehydrated, a dark line is observed to enter the flake at the edges and gradually converge on the centre. Inspection under the microscope reveals that the first moving boundary is followed by a second which is much fainter and travels at a slower rate (Fig. 1). These boundaries represent wave-fronts of water molecules diffusing into the crystal. The first and stronger of the two is caused by a phase change corresponding to an expansion of the lattice in the *c*-direction from 11·59 A. to 13·82 A., and the second by a smaller lattice expansion from 13·82 A. to 14·36 A.[2]. The reverse process, namely, dehydration, is rather more difficult to observe.

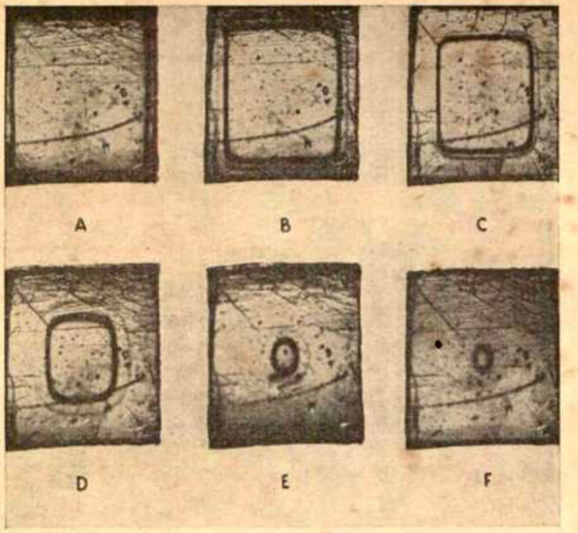

Fig. 1. Photographs taken at intervals during the diffusion of water molecules into a partially dehydrated magnesium vermiculite crystal

It is evident from Fig. 1 that the rate of diffusion in the plane of the layers for each phase-change is equal in all directions. Perpendicular to this plane the diffusion is effectively nil. Rate measurements indicate that the distance travelled is proportional to the square root of the time taken, in agreement with the requirements of the theory of diffusion. With a flake 2 mm. square, rehydration takes several minutes at 20° C. and 50 per cent relative humidity. The appearance of the crystal in section at an intermediate stage of the hydration process is shown diagrammatically in Fig. 2. Considerable distortion of the silicate layers must occur at the phase boundaries, especially where mutual displacements of the silicate layers are involved as in the 13·82 A.–14·36 A. transition. The elasticity of the silicate layers is evinced by the fact that the process may be repeated a number of times without appreciable diminution in the sharpness of the boundaries.

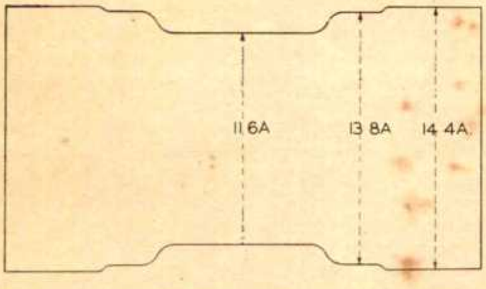

Fig. 2. Sectional diagram of a magnesium vermiculite crystal at an intermediate stage of rehydration (approximately to scale)

Under suitable conditions, the formation of organic complexes can also be followed by this method.

Electroluminescence in Disordered Zinc Sulphide

IN recent times a detailed study has been made of the structure of zinc sulphide crystals[1], and of the solid-state properties, particularly electroluminescence[2], of this compound. Of the many factors which may influence the electrical and optical properties of zinc sulphide, little attention has so far been paid to the effect of the modifications which can occur in the crystal structure. In addition to the well-known cubic (sphalerite) and hexagonal (wurtzite) forms, single crystals of zinc sulphide can also be obtained with a one-dimensional stacking disorder of the hexagonal (0001) planes[3]. This disorder may exhibit a periodic arrangement resulting in the formation of polytypes[1]. Although no experimental work seems to have been published linking electroluminescence with disorder, Schneer[4] has, from theoretical considerations, suggested that there may be some connexion; in addition, the electroluminescent properties of some zinc sulphide phosphors have been tentatively ascribed to a partial transformation from hexagonal to cubic[5].

Experiments in these laboratories have led us to believe that electroluminescence both in single crystals and in powders may be associated, in some circumstances, with the phenomenon of one-dimensional disorder. Needle-shaped crystals of zinc sulphide, prepared by a sublimation technique and activated by thermal diffusion of copper from the crystal surface, were seen to exhibit parallel streaks of blue electroluminescence in a manner very similar to that described by Diemer[6]. Examination under the polarizing microscope, between crossed nicols, revealed bands of interference colours; from an X-ray examination these bands were found to be perpendicular to the *c*-axis of the crystal, and to originate from random one-dimensional stacking disorders. The electroluminescent streaks were observed to be strictly parallel to these colour bands; this is clearly demonstrated in the accompanying photographs. In Fig. 1*a* a crystal between crossed nicols is shown, the interference colours appearing, of course, as different shades of grey; Fig. 1*b* is the light pattern produced in the region between the electrodes by an alternating field of 10 kc./s. The streaks of light are clearly parallel to the coloured bands, although not all the bands have an associated electroluminescent streak. Observations of the blue electroluminescent streaks and colour bands, simultaneously, give a precise confirmation of this parallelism, but in a monochrome photograph they would be indistinguishable. The pattern remains unchanged regardless of the alteration of the field direction produced by change of electrode positions; the overall brightness, however, does alter and is a maximum when the field is in the same direction as the streaks and bands.

A second batch of crystals, subjected to an identical activation treatment, had a higher apparent brightness, and optical and X-ray examination suggest a more extensive disorder. These crystals displayed many more light sources, both in the form of streaks and points, than were apparent in the needle-type crystals described above. The streaks of electroluminescence were again in alignment with the colour bands.

In the case of powders, it was found that, in a particular series of zinc sulphide – copper electroluminophors, maximum brightness was associated

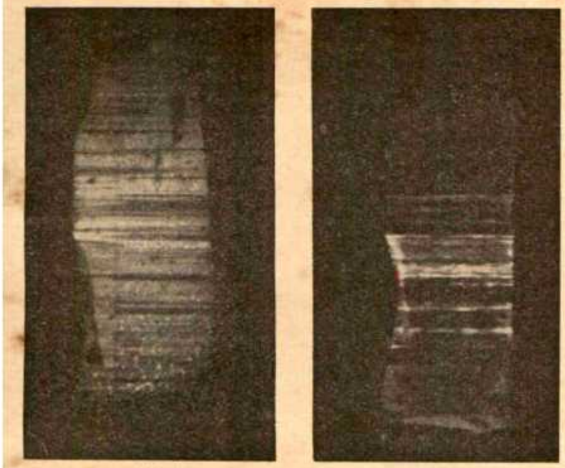

Fig. 1. Electroluminescent crystal of zinc sulphide activated with copper. (a) Between crossed nicols; (b) electroluminescence under 10 kc./s. Magnification, × 60

with a high degree of stacking disorder, as revealed by diffuseness in certain X-ray powder reflexions, and by single-crystal photographs of the constituent crystallites.

These observations may be explained by a non-uniform distribution of emitting centres or by a non-uniform electric field. In either case, the non-uniformity could be due to disordered regions, possibly because activator atoms diffuse readily along disorder boundaries. In this connexion it may be noted that some of the crystals which displayed blue electroluminescent streaks also luminesce under ultra-violet excitation. The ultra-violet luminescence is apparently distributed evenly throughout the body of the crystal, so that the centres involved are uniformly distributed. This perhaps supports the second possibility, although it is not certain that the luminescence originates at the same centres in the two cases.

Although disorder may not be a necessary condition for electroluminescence, particularly as both cubic and hexagonal electroluminescent zinc sulphide phosphors have been reported[2], these results suggest that a suitable environment of copper activator, such as is provided by boundaries between ordered regions of zinc sulphide, can provide conditions particularly favourable for electroluminescence.

It is perhaps significant that silicon carbide also possesses the dual properties of electroluminescence[2] and one-dimensional disorder[1].

The work is being continued and further results should help to assess the influence of crystal structure on the solid-state properties of zinc sulphide.

Empirical Relationship between the Excitation Energy of the *F*-band and Physical Constants for Alkali Halides

The excitation energy for a $1s - 2p$ transition in an electron associated with a hydrogen-type impurity embedded in a dielectric medium with high-frequency constant K_0 is

$$\frac{3}{8}\,\frac{e^2}{K_0 R} \tag{1}$$

where R is the Bohr radius, 0·529 A.

If R is taken as the radius of cation instead of the Bohr radius, then it is found empirically that the ratio of the excitation energy of the F-band to the expression (1) is close to unity for a large number of alkali halides containing F-centres.

The values of this ratio for various alkali halides are given in Table 1.

Table 1

Salt		LiF	LiCl	NaF	NaCl	NaBr	NaI
Ratio		1·0	1·0	1·12	1·06	1·06	1·08
Salt	KF	KCl	KBr	KI	RbCl	RbBr	CsCl
Ratio	1·24	1·16	1·13	1·17	1·20	1·15	1·64

The reason that the CsCl ratio differs from the other twelve ratios might well be due to its different crystal structure.

Values of R have been taken from Pauling, L., *J. Amer. Chem. Soc.*, **49**, 765 (1927), and those of K_0 from Hojendahl, K., *K. Danske Vidensk. Selskab*, **16**, No. 2 (1938).

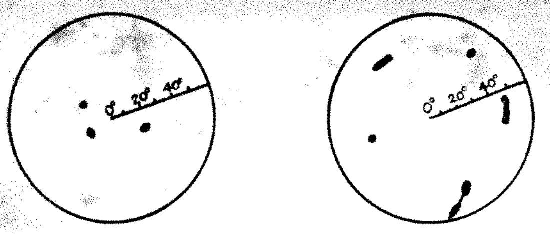
Deformation Characteristics of Hafnium

Because of its high nuclear cross-section, high melting point and good resistance to corrosion and oxidation, hafnium is being considered for practical application in the nuclear engineering field. Appreciable quantities of the material are being produced as a by-product of the production of pure zirconium.

Using small samples sectioned longitudinally from the periphery of hafnium crystal bar, the deformation characteristics of the material were studied. Cracking appeared when the metal was cold rolled 25–30 per cent total reduction. In spite of such precautions as previous vacuum annealing and small passes—1 per cent or less—10 per cent total deformation appeared to be the top limit which could be expected by cold rolling without intermediate annealing. Slightly elevated temperatures, however, seemed to make the material much more plastic. At 500° C., approximately 200° below the recrystallization temperature, the reduction by rolling was found to proceed to almost any practical reduction without cracking. Compression deformation was found to be possible to 90 per cent total reduction at 300° C.

Using a reflexion integrating pole-figure goniometer technique, the orientation of the deformed material after severe etching was studied, and on the basis of preliminary determinations was found to be very similar to the preferred orientations previously reported for titanium[1].



0001 pole figure   10$\bar{1}$1 pole figure

Fig. 1. Hafnium of 99·9 per cent purity after 78 per cent compression. Compression axis normal to plots

The compression texture was found to be [0001] rotated 15°–30° from the axis of compression. The basal plane rotation appeared to be predominantly around a 10$\bar{1}$0 rotational axis. A typical compression texture of a large-grain crystal bar material is shown in Fig. 1. Each 0001 peak would appear to be due to a single grain.

The rolling texture is very similar with the 0001 plane rotated 10°–25° around a 10$\bar{1}$0 rotational axis. Little or no directionality was apparent. In rolling at 500° it was noted that the sample increased considerably in width as well as in the rolling direction, indicating that this deformation may be similar in effect to compression deformation.

This type of texture could be accounted for by 11$\bar{2}$2 and 11$\bar{2}$1 twinning and 10$\bar{1}$2 twinning where the hexagonal axis is rotated from the compression axis and also by $\{0001\}$ $<11\bar{2}0>$ and $\{10\bar{1}1\}$ $<11\bar{2}0>$ slip.

We thank Mr. Roger Sutton, of the Argonne National Laboratory, and Dr. Earl Hayes, of the U.S. Bureau of Mines, for supplying the material used in this investigation, and Dr. Robert Gibney for making available the X-ray diffraction facilities of the Los Alamos Scientific Laboratory.

A Simple Tonometer

An apparatus has recently been developed in connexion with the work of linguists which promises also to be useful to investigators of speech in the deaf. Linguists who study tonal languages such as Chinese and many of the African languages have had in the past to rely almost entirely on the subjective process of listening, in order to determine the all-important pitch of each syllable. The oscillograph is not a practical proposition for dealing with thousands of words. Teachers of the deaf are faced with the fact that intelligibility depends not only on correct enunciation and rhythm, but also on the rise and fall of the voice. The latter accomplishment has proved too difficult save for the more gifted pupils, as it has been undemonstrable.

The tonometer I describe would appear to provide assistance to both these classes. It consists of three units—a microphone, an amplifier, and the tonometer itself. The two principles governing the apparatus are the sympathetic vibration of reeds, and the selective vibration of reeds. It consists of three units: the soundboard, the reed-bank and the oscillator. The soundboard is of wood, about 9 in. long and 3 in. wide, pivoted at both ends to allow of free vibration. On it is fixed the reed-bank. This is a metal comb with 66 slots to keep the reeds in position. On the rear side is a row of retaining screws to hold the back ends of the reeds. These have a triple suspension: each reed passes between three parallel metal bars running the length of the comb, over the first, under the second and over the third, and so on, the vibrating portion projecting through the teeth of the comb. Between the suspension and the holding screws is a metal bar through which pass the tuning screws, one to each reed. By adjusting these, the vibrating part of the reed is either lengthened or shortened. The reeds are spread over a range of two octaves, which allows for the speech-range of adult male speakers of differing natural pitch. The tuning for treble voices would be similar but higher. The tuning needs to be accurate, the distance between the reeds being 2 vibrations per sec. in the bass and 3–4 vibrations per sec. in the middle and high registers. This fine tuning necessitates a special technique described below.

The oscillator is a simple balanced-armature vibrator, the vibrator itself being coupled to the soundboard, and the oscillator connected to the amplifier.

The tuning was accomplished thus: gramophone records were made giving the pitch of each semitone required. The first reed (say *C*) was tuned from the record by sympathetic vibration, the radiogram loud-speaker circuit being connected to the oscillator. Then *C*♯ in like manner. The three intermediate reeds were tuned like this: when reed *C* was vibrating at maximum amplitude, the next reed above it was tuned to vibrate at half its amplitude, and the middle of the three reeds to about a quarter of its amplitude. The same was now done working backwards from *C*♯. If the behaviour of the reeds was uniform, the semitone was divided with sufficient precision. And so on for all the reeds.

A scale is fixed in front of the reeds giving the name of each semitone, and there are movable pointers to assist in plotting the moving reeds during speech.

When a person speaks, only those reeds (and their immediate neighbours) vibrate, the frequency of which is that of the sound produced by the speaker. Thus waves of movement are seen on the reed-bank and it is quite easy to watch the rise and fall of the voice. It is also easy to train oneself to reproduce on the reed-bank a given rise and fall demonstrated by another speaker.

It will be seen that here is an apparatus giving linguists an objective reading for speech intonation: it is also a means whereby teachers of the deaf can show by their own speech (for example, saying 'Good morning') how the voice should rise and fall, noting on the scale the appropriate intervals. Deaf pupils can practice until they produce on the tonometer the same intervals. They will thus be enabled to achieve that correct rise and fall of the voice which is essential to intelligible speech.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 6

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. W. W. Williams: "An East Coast Survey".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "What should be our National Fuel Policy?" Opening Speaker: Mr. E. F. Schumacher.

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Capt. H. F. Jackson: Presidential Address.

University College London (in the Chemistry Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. K. Alder (Cologne): "Some Recent Aspects of Diene Synthesis".*

Society of Chemical Industry, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Meeting on "Cost Accounting in the Chemical Industry".

Tuesday, February 7

Institution of Chemical Engineers (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. P. Fraser and Mr. P. Eisenklam: "Liquid Atomization and the Drop Size of Sprays".

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. A. R. Thomas: "Some Hydraulic Investigations in Connexion with the Wadi Tharthar Project, Iraq".

Physical Society, Acoustics Group (at the British Institute of Recorded Sound, 38 Russell Square, London, W.C.1), at 5.30 p.m.—Dr. W. H. George: "Determination of Tone-Colour".*

Scientific Film Association (at the Science Museum, South Kensington, London, S.W.7), at 6.30 p.m.—Dr. J. C. G. Gilbert: "Physics and Underwater Research".*

Society of Chemical Industry, Plastics and Polymer Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Prof. H. W. Melville: "A Study of the Chemistry of Radical Reactions by Radioactive Tracer Techniques".

Wednesday, February 8

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. E. M. Deloraine: "Pulse Techniques, with particular reference to Line and Radio Communication".

Society of Chemical Industry, Microbiology Group (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p.m.—Mr. W. D. Burnet: "The Manufacture of Whisky".

Thursday, February 9

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Dr. T. F. Macrae: "The Research Work of Glaxo Laboratories Ltd.".

Society of Instrument Technology, Control Section (at Manson House, Portland Place, London, W.1), at 6 p.m.—Annual General Meeting. Prof. A. Tustin: "The Scope for Feedback Control and Automatic Calculation in Industrial Mechanization".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. L. G. Fairhurst: "Propellers for Military and Civil Aircraft".

Thursday, February 9—Friday, February 10

Society of Chemical Industry, Food, and Oils and Fats Groups (at the Wellcome Research Institute, 183 Euston Road, London, N.W.1)—Joint Conference on "Recent Advances in the Knowledge and Uses of Phospholipids in Foods".

Friday, February 10

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting followed by Annual General Meeting.

British Psychological Society, Social Psychology Section (in the Electrical Lecture Room, University College, Gower Street, London, W.C.1), at 7.30 p.m.—Mr. C. Slaughter: "Some Psychological Implications of an Anthropological Community Study in England".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. J. F. Baker: "The Steel Skeleton".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Principal Scientific Officer (with a second-class honours degree or equivalent in chemistry or chemical engineering, and a knowledge of physical chemistry and of the aspects of physics and mathematics required for the analysis of chemical engineering problems) in the Research and Development Branch, Risley, near Warrington, Lancs, to take charge of a small group engaged on theoretical studies relating to the design and performance of chemical and process plant—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group H.Q., Risley, near Warrington (February 10).

Assistant Lecturers or Lecturers (2) in the Department of Physiology—The Registrar, The University, Liverpool (February 11).

Lecturer in Education—The Registrar, The University, Reading (February 18).

Assistant Lecturer in Zoology—The Principal, Royal Holloway College, Englefield Green, Surrey (February 20).

Deputy Director (with a degree in mechanical or chemical engineering and long experience in a research laboratory in a position of responsibility, and a knowledge of estimation, erection and operation of plants and machineries (including pilot plants)) of the Fuel Research Institute, Council of Scientific and Industrial Research, India—High Commission of India, Establishment Department, Aldwych, London, W.C.2, quoting 4/98A. (February 20).

Senior Lecturer in Psychiatry—The Registrar, The University, Manchester (February 20).

Lecturer (preferably with experience and research interests in statistical mechanics and thermodynamics) in Theoretical Chemistry in the Department of Physical and Inorganic Chemistry—The Registrar, The University, Bristol 8 (February 22).

Lecturer in the Department of Pathology—The Secretary, The University, Edinburgh (February 25).

Lecturer or Assistant Lecturer in Physics—The Registrar, The University, Leeds 2 (February 28).

Chemists and a Bacteriologist, for dairy laboratory work in New Zealand—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting A.3/4/47 (February 29).

Lecturer in Plant Physiology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, February 29).

Lecturer (preferably with research interest in semi-conductors) in Physics—The Registrar, The University, Nottingham (February 29).

Lecturer (preferably with special qualifications in ultra-high frequency techniques) in Electrical Engineering—The Registrar, College of Technology, Manchester 1 (February 29).

Official Fellow in Mathematics—The Warden, New College, Oxford (February 29).

Professor of Nuclear Physics—The Dean, Faculty of Science, Giza, Egypt (February 29).

Assistant Experimental Officer (preferably with a degree in botany or agricultural botany) in the Plant Pathology Department, for work on cereal diseases—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 109 (March 1).

Assistant Lecturer (with a special or honours degree in geology) in Geology (Palæontology), and an Assistant Lecturer (with a special or honours degree in mathematics) in Mathematics (including Geometry)—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (March 1).

Professor of Inorganic Chemical Technology—The Dean, Faculty of Engineering, Cairo University, Giza, Egypt (March 1).

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester 13 (March 10).

Assistant Lecturer or Lecturer in Mathematical Statistics in the Department of Applied Mathematics—The Registrar, The University, Liverpool (March 12).

Lecturers (3) in Geology—Secretary of University Court, The University, Glasgow (March 12).

Chair of Physics—The Secretary, The University, Exeter (March 15).

Lecturer in Microbiology—The Registrar, The University, Reading (March 24).

Chair of Physical Chemistry at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, March 26).

Chair of Physics at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (March 31).

Director (with a wide knowledge of plant pathology (particularly of tropical crops) and experience in research of the subject, administrative ability and experience, literary taste, and some knowledge of languages) of the Commonwealth Mycological Institute, Kew—The Secretary, Commonwealth Agricultural Bureaux, Farnham Royal, Bucks (May 31).

Assistant Conservator (with a university degree in forestry) of Forests, Sierra Leone—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.61/15/04.

Chemist (with a first- or second-class honours degree in chemistry or equivalent qualification and at least three years postgraduate research experience) with the Ministry of Supply at Farnborough, Hants, to take charge of a laboratory engaged in research and development work on textiles in relation to their use in Service equipment and clothing—The Ministry of Labour and National Service Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.37/6A/AA.

Chief Laboratory Technician in the Physics Department—The Secretary, Northern Polytechnic, Holloway, London, N.7.

Demonstrators in Physics and Demonstrators in Organic Chemistry—The Registrar, The University, Nottingham.

Experimental Officer (preferably with a degree in physics or mathematics and previous laboratory experience, or at least H.S.C. in science subjects or equivalent) in the Nuclear Physics Division, to take charge of the construction and operation of a neutron velocity selector for the new research reactor Dido—The Establishments Officer, U.K. Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 474.

Experimental Officer (with at least H.S.C. in science subjects or equivalent qualifications, a good general knowledge of physics with some idea of the basic concepts of nuclear physics, and preferably with several years experience in a physics laboratory) in the

Nuclear Physics Division, to help organize a small team working on the measurement of neutron spectra in reactors—The Director, Atomic Energy Research Establishment (Recruitment), Harwell, Didcot, Berks, quoting 484.

Instructor, Assistant Professor or Lecturer (preferably with a doctorate in physics or mathematics and an interest in nuclear or solid state physics) **in Physics**—The Chairman, Department of Physics, Western Reserve University, Cleveland 6, Ohio, U.S.A.

Lecturer in Agricultural Chemistry—The Principal, Shuttleworth College, Old Warden Park, Biggleswade, Beds.

Metallurgist (with a first- or second-class honours degree or equivalent qualification in metallurgy, and several years metallurgical research experience, preferably in the field of non-ferrous metals) at a Ministry of Supply Establishment at present in S.E. London, for research and development in the field of less common non-ferrous metals—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.18/6A/AA.

Physicists and **Electrical Engineers** (with a first- or second-class honours degree or equivalent in physics or electrical engineering) at the Ministry of Supply Radar Research Establishment, Malvern, Worcs, for research and development work, mainly on radar and electronic equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.490/5A/AA.

Principal Lecturer (with high academic qualifications, and preferably some industrial experience) **in Food Science**—The Secretary-Treasurer, Royal Technical College, George Street, Glasgow C.1.

Professors (with a post-graduate degree or diploma and considerable teaching experience) **of Anatomy, Physiology, and Pharmacology**, at a new Medical College to be established at Chittagong, East Bengal—The Recruitment Officer, Education Division, Pakistan High Commission, 39 Lowndes Square, London, S.W.1.

Radiographer in the X-Ray Diagnostic Department—The House Governor, Westminster Hospital, St. John's Gardens, London, S.W.1.

Scientific Officers (with at least a second-class honours degree in chemistry or equivalent qualifications) and **Experimental Officers** (with H.S.C. in science subjects, including chemistry or equivalent qualifications, together with some experience in inorganic chemistry or analysis), to work on the development of methods for carrying out special inorganic chemical preparations and of techniques for depositing thin films by a variety of physical and chemical procedures—Establishments Officer, U.K. Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting reference 472

Senior Lecturer in Metallurgy; **Assistant**, Grade B, **in Mechanical Engineering**; and **Assistants**, Grade A, **in** (*a*) **Chemistry** and (*b*) **Structural Engineering**, at Constantine Technical College—The Director of Education, Woodlands Road, Middlesbrough.

Senior Metallurgist, Principal Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree in metallurgy or equivalent qualification, preferably with experience of failure investigations, a good knowledge of metallography and at least three years postgraduate research experience) at the Royal Aircraft Establishment, Farnborough, Hants, for metallurgical investigations of failures and defects in aircraft parts, and to take part in the metallurgical research of the department—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting F.12/6A/AA.

Senior Scientific Officer (with a first- or second-class honours degree in physics, and at least three years postgraduate practical experience of electronics with the ability to apply it to research problems) to lead a small team engaged on novel physical research problems involving the techniques of mass spectrometry and radioactive measurements—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 1001/34.

PERMUTIT **ION EXCHANGE MATERIALS**

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

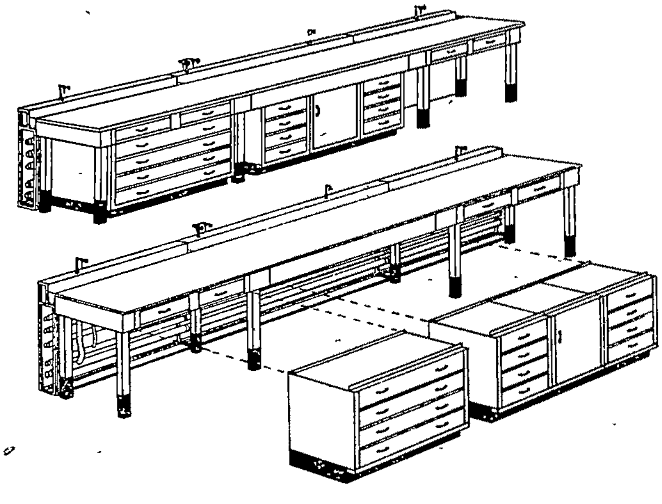
Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials — Made in Britain by British Labour

a NEW *range of* LABORATORY UNIT FURNITURE

AND PREFABRICATED SERVICE RACKS



The *flexibility, economy* and *general usefulness* of *UNIT* furniture are advantages which cannot be disregarded.

We offer standard benches of modern design and construction, with removable units, in metal; and standard service racks which will connect up to supplies (electricity, gas, water, steam, etc.) provided at any *one* point in the Laboratory. May we tell you more about them ?

LECTURES AND COURSES

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

ACTON TECHNICAL COLLEGE

HIGH STREET, ACTON, W.3

Principal: J. Topping, M.Sc., Ph.D., D I C., F.Inst.P.

DEPARTMENT OF CHEMISTRY AND BIOLOGY

Head of Department: J. H. Skellon, T.D., M.Sc., Ph.D., F.R.I C.

POSTGRADUATE COURSES SESSION 1955-56

A Short Course of Lectures on

CHEMICAL AND RADIOLOGICAL HAZARDS IN INDUSTRY

is being held in the Department on Fridays at 7.30 p m.

Lectures from February 3 include: Radiological Hazards—Some Physical Aspects (February 3). Insecticides (February 10). Flour Treatment by Agene (February 17). Practical Radiation Protection (February 24). Fluorosis (March 2)

Lecturers are specialists from University Departments or Research Associations. Fee: One to Five Lectures 10s.

Further particulars and application forms may be obtained from the Principal.

C. E. GURR, M Sc., Ph.D.,
Secretary to the Education Committee.

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON)

SESSION 1956-1957 BEGINS MONDAY OCTOBER 1, 1956

Part-time (Evening) Courses provided for Internal Degrees in the Faculties of Arts and Science and for the Academic Postgraduate Diploma in Psychology. Facilities also provided for part-time and full-time students reading for higher degrees in arts and science. Applications for admission should be made before June 1.

Pamphlet and form of application may be obtained from the Registrar, Birkbeck College, Malet Street, W.C.1.

UNIVERSITY OF BRISTOL

DIPLOMA IN HORTICULTURAL SCIENCE

A course for the above postgraduate Diploma will commence on September 10, 1956. It extends over a full university session of three terms ending in the following June or July. Conducted in part at the Long Ashton Research Station, it is intended primarily for those with good honours degrees in science who seek careers in horticultural research, at home or abroad.

Early application should be made to the undersigned, from whom full particulars may be obtained.

H. C. BUTTERFIELD,
Registrar and Secretary,

The University,
Bristol, 8.

UNIVERSITY COLLEGE

LONDON

GOWER STREET, W.C.1

Applications for admission to the B.Sc. (special) course in Zoology commencing in October 1956 must reach the Tutor to Science, Students not later than Saturday, February 25, 1956. Selected applicants (who will be notified individually) will be required to take a written and practical test in the Department of Zoology on Thursday, March 22, 1956, from 10 a.m. to 5 p.m. The final selection of candidates for admission will, with certain rare exceptions, be made from those successful in this test.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

UNIVERSITY OF GLASGOW

Research Assistant wanted in Biochemistry Applicants should hold the degree of B.Sc or the A.R.I.C. or have equivalent experience

Applications should be sent as soon as possible to Professor Davidson, Biochemistry Department, The University, Glasgow, W 2.

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to the Chair of Physical Chemistry in the University's Department of Chemistry and Chemical Engineering, this being the second Chair in the Department. The Professor of Physical Chemistry will be responsible to the Head of the Department, who is also Professor of Organic Chemistry, for the courses he is called upon to give in physical chemistry and related subjects. Duties are to be assumed on August 1, 1956, or as soon as possible thereafter. The substantive salary scale attached to the appointment will be £1,650 by £50 to £1,950. In addition a married man will receive cost of living allowance at such rate as may be authorized from time to time, the present rate being £234 per annum. Membership of the Provident Fund is compulsory. Membership of the Staff Medical Aid Fund is compulsory in the case of an officer who is found eligible for such membership

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in London and South Africa, is March 26, 1956.

UNIVERSITY OF GLASGOW

LECTURESHIPS IN GEOLOGY

Applications are invited for three Lectureships in Geology (one in geophysics, one—which may be a Senior Lectureship—in igneous petrology) Salary scale: Senior Lecturers £1,400 by £50 to £1,650; Lecturers £650 by £50 to £1,350. F.S.S.U. and family allowance benefits.

Applications (5 copies) should be lodged, not later than March 12, 1956, with the undersigned, from whom further particulars may be obtained

ROBT. T. HUTCHESON,
Secretary of University Court.

UNIVERSITY OF GLASGOW

LECTURESHIP IN GENETICS

Applications are invited for a Lectureship in Genetics. Salary scale: £650 by £50 to £1,350. Initial salary according to experience and qualifications. F.S.S.U. and family allowance benefits.

Applications (8 copies) should be lodged, not later than February 11, 1956, with the undersigned, from whom further particulars may be obtained

ROBT. T HUTCHESON,
Secretary of University Court

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for the following vacancies: (i) Two Assistant Professorships, Nuclear or Solid State Physics or Spectroscopy (ii) One Instructorship. (iii) Two Post-doctorate Research Fellowships. First inquiries should be accompanied by brief particulars regarding training and experience

Full information regarding these vacancies may be obtained from G M Shrum, Department of Physics, University of British Columbia, Vancouver, 8, B.C., Canada.

ADMIRALTY, ROYAL NAVAL SCIENTIFIC Service. Engineers and Physicists (particularly with Electronics) required in Experimental Officer and Assistant Experimental Officer grades in Experimental Establishments in London, Portsmouth, Weymouth areas Gloucestershire and Scotland. Qualifications, British subjects, minimum of higher school certificate (pass degree, higher national certificate or near equivalent an advantage). London salary (men) Experimental Officer £790 to £960. Assistant Experimental Officer £320 10s. to £700 (according to age). Appointments unestablished, but opportunities to compete for established posts. —Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A214/5A.

CHESTER BEATTY RESEARCH INSTITUTE, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, S.W.3. Organic Chemist required, interested in synthetic work in the field of cancer research (cytotoxic agents, antimetabolites, anti-hormones, enzyme inhibitors). The post is permanent and superannuable, and salary will be according to age, experience and qualifications. Applications, giving the names of two referees and marked "FB/T," should be addressed to the Secretary.

WEST AFRICAN INSTITUTE FOR OIL PALM RESEARCH, NIGERIA

Applications are invited for the post of RESEARCH ENGINEER, at the WEST AFRICAN INSTITUTE FOR OIL PALM RESEARCH.

Duties are primarily research and development in connexion with engineering problems, particularly those arising in the processing of oil palm fruit in plantation oil mills of various kinds. The Officer will be required to work in close collaboration with other members of the Institute staff concerned with the production of the crop in the field and will be required to modify existing plant or design new.

Appointment is either pensionable or on contract in the gross salary range £1,292 10s. to £2,437 10s. per annum, with a gratuity of £122 to £275 10s. per annum in the case of a contract appointment.

Free passages are provided for the officer, his wife and all children under 13 years of age. Furnished Government quarters are provided if available at a rental of 10 per cent basic salary subject to a maximum of £150 per annum. Leave is granted at the rate of 7 days for each completed month of resident service.

Candidates, not less than 26 years of age, should hold a good honours degree in Mechanical or Chemical Engineering, and have had at least 3 years postgraduate experience in the design and operation of plant for vegetable oil extraction and processing. They must possess a "research outlook" and should be well versed in the critical appreciation of practical problems from a scientific angle. They must be well qualified engineers with a particular aptitude for mechanical matters, and have a good knowledge and experience of chemistry

Apply, in writing, to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number BCD 197/199/01.

QUEEN ELIZABETH COLLEGE

(UNIVERSITY OF LONDON)

CAMPDEN HILL ROAD, W.8

Biochemist or biologist required as research assistant in problems of nutrition and fertility, involving chiefly experiments with laboratory animals Salary between £700 and £1,000.

Apply in writing to the Secretary.

MOUNT VERNON HOSPITAL

NORTHWOOD, MIDDX.

Technician required for the Physics Department Workshop The workshop constructs and repairs research equipment. Applicants should have experience of all machining processes and be able to work from rough sketches. The appointment will be made within the scale (at present under review), commencing £485 per annum plus London Weighting (age 21-25, £20; 26 and over, £30)

Applications giving age and past experience should reach the Secretary and House Governor, by February 25, 1956

GOVERNMENT OF INDIA

MINISTRY OF PRODUCTION

Applications invited for post of a Chief Engineer, in India, for Nangal Fertilizer-Heavy Water Project, on a salary up to £2,700, for an exceptionally qualified candidate. Applicant must have training in the design of chemical plant and about ten years' experience in the erection and maintenance of industrial plants, preferably for the manufacture of ammonia and fertilizers. Age preferably above 45. Initial appointment is on contract but may be made permanent.

Supplementary information and forms of application from High Commission of India, Establishment Department, Aldwych, London, W.C.2, quoting 202/9/21E. Last date for receipt of applications February 29, 1956.

SOUTH AUSTRALIA

SCHOOL OF MINES AND INDUSTRIES

Applications are invited for the position of Lecturer in Physical Chemistry, Department of Mining, Metallurgical and Chemical Engineering, Adelaide Qualifications: Honours degree in Physical Chemistry or equivalent. Experience: Postgraduate experience in industry or academic research would be an advantage. Appointment covers (a) lecturing in advanced physical chemistry in degree and diploma courses, and (b) research work which may be directed to securing a higher degree Salary Range: £1,525 to £1,650 Australian.

Applications and enquiries to be addressed to: Agent General and Trade Commissioner, South Australia House, Marble Arch, W 1. Closing date for applications February 27, 1956.

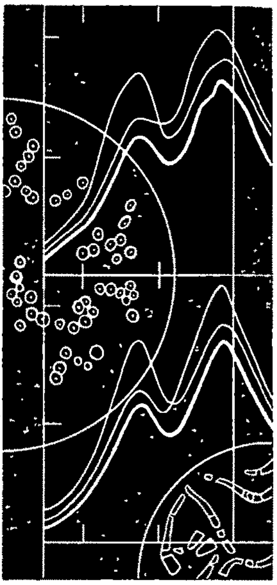
BOOKS ON SPECIALIZED SUBJECTS

Books on science, research, electronics, industrial work, electrical and mechanical engineering can be quickly supplied through your local Smith's shop or bookstall. College and works librarians and students, particularly, are invited to ask for lists of books on any subject. Any books not stocked locally will be quickly obtained from Head Office.



Your stationery and printed matter can also be supplied through our local branch.

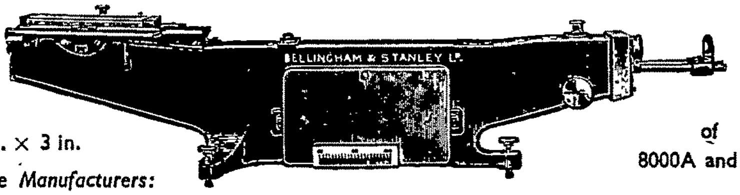
PRECISION B&S INSTRUMENTS

***Spectrograph** with quartz optical system*

Critical definition is obtained over the entire range of the spectrum. Size of photographic plate 12 in. × 3 in.



A larger instrument can now be supplied giving a 12 in. length of spectrum between 8000A and 2100A.

Full particulars from the Manufacturers:
Bellingham & Stanley Ltd. DEPT. N, 71 HORNSEY RISE, LONDON, N.19

PRESERVATION OF THE COUNTRYSIDE IN BRITAIN

EVEN a cursory reading of the sixth annual report of the National Parks Commission, which reports to the Minister of Housing and Local Government, and that of the Nature Conservancy, which reports to the Lord President of the Council, cannot fail to reveal how much the two bodies have in common (see p. 264 of this issue). The latter is essentially a scientific body, the work of which is of profound importance to agriculture and forestry, water supply, coastal defence and meteorology, and for decisions about the use of land in general. None the less, sound policies of conservation depend at every step on scientific research carried out in intimate contact with land management and advisory and educational work, and the Conservancy is already finding it increasingly difficult to maintain a policy of free access in face of thoughtlessness and destructiveness on the part of a minority of the public. The National Parks Commission likewise finds increasing need for public support and understanding and, at the Conference of Park Planning Authorities which he convened last July, the Minister of Housing and Local Government said that in the end the only sure guardians of the national parks are the people themselves; national parks will be assured of the money they need and safe against encroachment or mutilation to the extent that the public visits them and values them.

What are required above all, by the Nature Conservancy no less than by the Park Planning Authorities and the National Parks Commission, are the support, encouragement and stimulus of an informed and critical public opinion; and these must come, not merely from the comparatively small number of enlightened workers in the open-air and scientific societies, to whom the Commission and Conservancy and the country at large owe so much, but also from an awakened public conscience throughout Britain. This is as true of the work of both bodies generally as it is in respect of problems, such as the study of the restoration, or even the maintenance, of the Broads, which they are handling in collaboration. The creation of local nature reserves or the voluntary action by national and county trusts and societies, for which the Nature Conservancy pleads, can only come as a result of that understanding and support.

Both reports contain encouraging evidence of the growth of such understanding and of increasing willingness to co-operate, just as they indicate how much more is required. The proper enforcement of the Protection of Birds Act, 1954, which is of vital concern to the Conservancy, on account of its responsibility for nature reserves and other areas which are or will be sanctuaries, ultimately rests on the inculcation of a wider understanding and knowledge of birds. The response to the Conservancy's letters to owners of sites of special scientific interest, however, has been most encouraging and appears to testify to the existence of a large fund of goodwill and readiness to co-operate, although in Scotland only a start has been made with such notifications and systematic notification in Wales has not yet begun.

The National Parks Commission regards its expanding activity in the field of information and publicity accordingly as of primary importance, and this is no less true of the Nature Conservancy. In this field of education it is probable that the official efforts of the two bodies could be supplemented by that of voluntary bodies such as the open-air societies and various scientific societies, both professional and amateur. The efforts of such bodies are, however, limited, like that of the Conservancy and the Commission themselves, by lack of finance, and here we touch on a second common note in both reports.

The Nature Conservancy points out that, as was forecast last year, its meagre grant-in-aid of £154,500 was quite inadequate for a programme of scientific work that already promises to yield returns within even a few years that will write off its cost many times over. Work on the fencing of reserves and on long overdue woodland operations has had to be postponed, as well as surveys and experiments, and grants for scientific studies and for postgraduate training had to be cut to an entirely inadequate level while the burden of rehabilitating and bringing into a satisfactory state of management even the existing reserves is rapidly increasing.

This failure to provide the necessary funds for research and conservation, including the acquisition of nature reserves, must result in loss or damage which will be felt by science and by the community many years after the transient minute saving in the current national budget has been forgotten. The point is not laboured by the Nature Conservancy, which is largely content to let its scientific record speak for itself; but it says little for the Lord President of the Council or the Committee of the Privy Council for Agricultural Research and Nature Conservancy, that the challenge presented no less clearly and firmly in the Conservancy's previous report has received no comment during the year. The position of the Nature Conservancy in the nation's organization for research appears to be long overdue for reconsideration, and should be pressed in the debates on the Agricultural Research Bill now before Parliament.

The matter is one which might well receive urgent attention from the Parliamentary and Scientific Committee, for an adequately financed Nature Conservancy is in a position to contribute out of all proportion to magnitude of effort. Both in ecological research and in conservation, success depends upon the fullest understanding and team-work between specialists who, but for the Conservancy, with its comprehensive responsibilities, might never meet. Already, with scanty resources, the Conservancy can report encouraging progress in promoting contacts, in initiating ecological studies and filling gaps, with benefits to biological research at the universities as well as to the Conservancy's own work; and it should not be overlooked in this connexion that the main recommendation from an inspection of the Conservancy's administration which the Organization and Methods Division of the Treasury was invited to make during the year was that conservancy should be recognized as the central executive task of the Conservancy, thus reducing the conflicting responsibilities of research scientists in applied scientific fields.

The responsibility for seeing that the financial needs of the Nature Conservancy are adequately met thus clearly lies with the Lord President of the Council; but scientists working in related fields also have a responsibility for seeing that their professional bodies make effective representations on the matter to the appropriate research councils. The financial needs of the National Parks Commission are also acute; but the position is entirely different and the prospects of an early improvement appear to be somewhat brighter provided effective public support is forthcoming. It will be noted that the report of the National Parks Commission gives no information on finance, although it is made plain year after year that the difficulties in administration arise mainly because the cost of administering and improving or safeguarding the national parks has been thrown essentially on the local authorities. The Commission has never been provided with funds of its own adequate, for example, to pay the cost of some measure required to safeguard amenity in a park area, which it is manifestly unreasonable to expect an individual owner or even a local authority to bear unaided, even if they had sufficient resources.

The purposes for which the Exchequer may pay grants amounting to 75 per cent of the total are detailed in the National Parks and Access to the Countryside (Grants) Regulations, 1954; but when it is realized that even a park authority warmly commended by the Commission for its activity and vigilance, such as the Peak Park Planning Board, spent less than £1,000 out of £27,000 on positive functions, thus qualifying for grant in the period April 1952–March 1954, and that the estimated expenditure of the Commission in 1953–54 was only £21,114, the parsimony with which the national parks in Britain are treated is obvious. In an earlier report the Commission had even had to record its inability to find the funds for printing the 'Country Code'.

The Conference of Park Planning Authorities last July also discussed a proposal that legislation should be introduced to make available from the National Land Fund moneys to be applied for national parks purposes. In July 1954 a report from the Committee on Public Accounts had recommended to the Treasury consideration of the desirability of legislation to return to the Exchequer some part of the large and growing balance of the National Land Fund, as being in the Committee's view a substantial amount of public money for which there was no foreseeable need. In 1946 the then Chancellor of the Exchequer had specifically mentioned the possible use of the fund for national parks purposes, and the Commission now expresses the view that use of such moneys in this way would be in line with the original intention of the Fund and provide an earnest of the Government's positive interest in national parks. It believes that if a specified sum were made available annually for a number of years ahead, both the Park Planning Authorities and the Commission could make forward plans on long-term projects, and initiate and promote a really effective national parks programme.

These views were urged on the Minister by the Commission in a letter dated February 24, 1955; but the Minister replied that the suggested provision could not be provided in the 1955 Finance Bill but would require a special Act. It is proposed accordingly to press the Minister to find some way by which grants from the Fund can be made available, and in the meantime some suggestions are made for amendment of the National Parks and Access to the Countryside Act, 1949, which should go far to remove this main weakness of the Act—not so much that the principal responsibility for administration of the parks should rest with the local authorities as that the financial burden should be borne by them. The Commission would remove, for example, the 75 per cent limit on the maximum grant and extend the purposes for which grant is payable to include, for instance, the creation of new footpaths and bridleways, the maintenance of warden services, the organization of information services, and anti-litter work. It also suggests that contribution should be payable to a developer in a national park area in respect of additional expenditure incurred by reason of conditions attached to planning consent in the interest of amenity, and that grants should also be permitted toward the administrative expenses of park planning authorities and towards administrative expenses incurred by local authorities in completing long-distance routes.

The Commission believes that amendment of the Act of 1949 on these lines and financial provision from the National Land Fund would give a new impulse to the creative side of national parks administration, the beneficent results of which would soon become apparent. Adequate financial provision, however imperative and beneficial, would not in itself remove the chief danger which threatens the work of both the Nature Conservancy and the National Parks Commission. That danger is the encroachment on national park areas and nature reserves, whether contemplated or already designated or declared, by the Service departments, the public corporations and even local authorities. The two most glaring instances cited in the present report are the decision of the Derbyshire County Council in principle to support a private Bill in the House of Commons for the establishment of a motor-racing circuit on public roads in the Peak District National Park, and the Manchester Corporation's objections to the route of the Pennine Way in the Longdendale valley.

The National Parks Commission, having inspected two alternative proposals by the Derbyshire County Council, is unable to see how any possible proposals would be consistent with the maintenance of the area as a national park. The action of the Derbyshire County Council can, of course, be rectified by alert public opinion when at last the Bill is presented to Parliament, and such public opinion, as Mr. Duncan Sandys has pointed out, is the only ultimate safeguard. In the Longdendale dispute, the Minister has upheld the contention of the Manchester Corporation, in the face of the sustained protest of the National Parks Commission; with an alert and informed public opinion, the proposal would never have been made.

The irruption of party politics into local government may be one factor that has made the larger local authorities less alert and responsive to the claims of amenity and nature conservation than they should be. The major threats, however, still come from the Service departments and the large public corporations, although both the Nature Conservancy and the National Parks Commission in these reports refer to an increasing readiness of the Service departments to consult with them on their proposals and to steps taken to facilitate consultation at the earliest possible stage. None the less, at the close of the year, the Conservancy was objecting to a number of major projects, adoption of which would involve heavy damage to the scientific interest of St. Kilda and Loch Druidibeg in the Outer Hebrides, the geologically important parallel roads of Glen Roy in Inverness, Bilston Glen in Midlothian, the fine beech woods near Aston Rowant and the important Breckland area at Cavenham Heath. There is also concern as to the effect on wild life of the decision of the Central Electricity Authority to build an atomic power station on the Severn Estuary within six miles of the Wildfowl Trust directed by Mr. Peter Scott, and another at Bradwell, on the River Blackwater, which is the wintering ground of a high proportion of the brent geese in Europe.

The threat to the proposed nature reserve in South Uist and to St. Kilda arises from the proposed Hebridean guided missiles range announced by the Government on July 27. In reply to a question in the House of Commons on October 25, the Minister of Defence stated that safety requirements demanded that a guided missiles range should be in a less populated area and also avoid congested air and shipping routes and extensively fished areas; it must also be associated with radar and airfield facilities. These considerations narrowed the choice of sites in the United Kingdom to the Outer Hebrides, and South Uist had been selected after a reconnaissance of the islands there. When specific proposals had been formulated in the light of the survey now proceeding, the interests concerned would be given the opportunity to lodge objections and a public local inquiry would be arranged if necessary.

This statement, and the subsequent debate in the House of Lords on October 27, reveal the inherent weakness of the existing procedure, under which, in effect, the Service departments are judges in their own cause, and the dilemma with which we are increasingly confronted in a small island such as Great Britain. As Lord Polworth remarked in opening the debate, the needs of defence must take first place; but he challenged the view that technical needs must have absolute priority on every occasion. There are other values in our civilization which the Services exist to defend and preserve. Pressed to an extreme, claims on land could leave us with nothing worth defending.

The scientific, as well as the cultural, interests affected by the proposal were emphasized by Viscount Elibank and by the Earl of Haddington, who referred to the importance of South Uist as a breeding ground for such rare birds in the British Isles as the red-necked phalarope and the hen harrier, and for more than half of our greyleg geese, and of St. Kilda for the Manx shearwater, Leach's petrel and puffins, as well as the archæological importance of South Uist. Lord Carrington, who replied, was content, however, rather to argue the value of a range in Britain instead of overseas than to answer either the social, cultural or scientific objections; though he acknowledged the need to preserve undisturbed as far as possible the wild life of the islands.

Lord Polworth withdrew his motion, but the particular project clearly calls for further discussion; and, if it is essential for the project to proceed, the Government would be wise to deal with the general issue in such a way as to facilitate carrying with it general consent of the country. If proposals involve not merely the disturbance of a particular community but also the destruction of an irreplaceable cultural and scientific heritage, it is important that the decision should be seen to be justified on full consideration of all that is involved and of what the scientific implications may be. Such decisions can never be easy, but too great care cannot be taken to remove all grounds for the suspicion that the judgment may have been made by some interested party without adequate regard to its implications in other fields. Public opinion remains the ultimate safeguard; but the Government could do more to promote the formation of an informed public opinion, and to remove the undoubted danger that difficult decisions of this kind may spread a wave of defeatism and disappointment that offsets much of the advantage to defence inherent in the decision.

LANGUAGE OF THE EMOTIONS

The Expression of the Emotions in Man and Animals

By Charles Darwin. Pp. xi+372+15 plates. (New York: Philosophical Library, 1955.) 6 dollars.

THE scientific study of expressive movement and action began with Sir Charles Bell's famous "Anatomy and Philosophy of Expression", first published in 1806. Important contributions from the Continent of Europe did not come until half a century later, in the work of Duchenne (1862), Gratiolet (1865) and Piderit 1867). Darwin's own studies of expression date at least from 1838, although his book was not published until 1872. Continental scholars, especially students of the origin and development of language, have shown a sustained interest in this subject; but since the work of Darwin there is little to report from Britain, perhaps because the demeanour of the natives is less demonstrative than it is across the Channel.

Darwin's investigation is marked by the comprehensiveness of his sources as well as by an acute sensibility in detecting the finest nuances in human expression. His data consist of observations of infants, the aged, the insane, the commoner animals, photographs, and paintings and sculptures of the great masters. This is supplemented by reports on the behaviour of diverse ethnic groups and cultures obtained from thirty-six observers living in Australia, China, India, Africa and North and South America.

The origin and development of all the expressive actions in man and animal he attempts to explain by means of three principles: the principle of serviceable associated habits; the principle of antithesis; and the principle of the direct action of the nervous system on the body.

Judged by present-day standards of statistical technique, his methods of sampling and of drawing inferences would perhaps scarcely be considered adequate. We do not share his faith in "associationism". Nor would we speak of "thrills of nerve-force" or of the inheritance of tricks and gestures. Yet somehow his conclusions do not seem any the less convincing; the high quality of his initial observations appears to make up for any lack in quantitative precision. The idea that a flood of new cybernetic light would be thrown on his subject by substituting 'communication' for 'expression', as seems to be implied by Dr. Margaret Mead in her preface, is perhaps a little sanguine.

Blushing, to which Darwin devotes an entire chapter, seems to him to stand in a class apart. He regards it as the most peculiar and the most human of all expressions. We cannot cause a blush by physical means—that is, by any action on the body. The mind must be affected: "thinking what others think of us, excites our blushes". We do not expect him to accept Burgess's view that blushing was specially designed by the Creator in order "that the soul might have sovereign power of displaying in the cheeks the various internal emotions of the moral feelings". The hypothesis he prefers rests on his belief that our powers of attention can influence the capillary circulation. He cites many eminent anatomists and physiologists, including Holland, Laycock, Carpenter, Paget and Johannes Müller, in support of his view that attention or consciousness concentrated on any part of the body produces some direct physical effect on it. But he admits that the means whereby attention—"perhaps the most wonderful of all the wondrous powers of the mind"—is affected is an extremely obscure subject. How far removed he is from those who believe that consciousness and attention are nothing more than occult qualities gratuitously introduced into the palpable world of anatomical 'reality', a world in which one is at most permitted to say that "the brain makes up its mind"!

He concludes that expressive actions are in general inherited and that only a few expressive movements, such as those of the hands in prayer, are learnt. The fact that the chief expressive movements are the same throughout the world he regards as affording an argument that we are descended from a single parent-stock, which must have been almost human before the divergence of the "races".

It is to be hoped that this new edition of Darwin's work, which has not by any means yet received the study it deserves, will serve as a reminder that there is an inner life of human emotion of which actions and gestures are simply manifestations. The scientific study of emotional experience is therefore not merely the lining of physiology.

JOHN COHEN

AMERICAN METHODS OF MATERIALS TESTING

The Testing and Inspection of Engineering Materials
By Prof. Harmer E. Davis, Prof. George Earl Troxell and Prof. Clement T. Wiskocil. (McGraw-Hill Series in Civil Engineering.) Second edition. Pp. xv+431. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 49*s*.

THE testing of materials is a fundamental necessity at some stage in all manufacturing or constructional processes. To what extent it can be treated as a particular subject for a course of instruction depends, of course, upon the educational establishment concerned. This book has been written as a text-book for such a course. The authors state in the preface that it is their aim "to provide a general treatment of the principles and problems of testing with specific reference to the mechanical properties of engineering materials and to establish the basis for the inspection of these materials". As such, it is a good review of mechanical testing in a wide form and has a very comprehensive reference list. It is written for Americans and refers entirely to standard specifications in the United States; hence there are limitations on its usefulness in Great Britain.

Two introductory chapters deal with the nature of the problem and the general features of mechanical testing. In Chapter 2, one is immediately struck by the difference in American and British practice by the use of 'yield strength' instead of the synonymous 'proof stress'. Chapter 3 covers load and strain measurement and inspection gauges. A notable omission in the otherwise comprehensive survey of strain gauges is the vibrating wire gauge.

Static (that is, tensile, compressive, etc.) tests are covered in great detail in the next two chapters, and hardness tests in Chapter 6. The Vickers diamond-pyramid hardness test, however, receives only half a page. Chapter 7 deals with impact tests and has certainly been brought up to date by reference to recent work on the dependence on temperature of notch brittleness of steels.

Fatigue and creep are the subjects of Chapter 8, but are covered very briefly compared with previous subjects, having only twenty-four pages devoted to them. On p. 220 the authors state the well-known fact that duralumin does not show a well-defined endurance limit, but then quote a value for it on p. 221. Non-destructive methods of flaw testing are outlined in Chapter 9 and include visual, X-ray, γ-ray, magnetic, electric and ultrasonic methods. Chapter 10 is a useful chapter on analysis and presentation of data and mainly deals with elementary statistics of observation. Chapter 11, entitled "The Principles of Inspection", deals with the organizational aspect of the problem and is concerned with the inspector, his qualifications, duties and responsibilities.

Part 2 is a section on laboratory work in testing and inspection, and outlines a series of twenty-four exercises that would make a suitable course. The appendixes include a brief summary of the principal mechanical properties of the more-important metals and non-metallic constructional materials. The book would form a good guide to a technical college course on mechanical testing, but would not be suitable in a university curriculum except as a reference book to American methods. K. J. Pascoe

DETERGENTS IN THE FACTORY

Industrial Detergency

Edited by Wm. W. Niven, Jr. Pp. iv+340. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1955.) 70*s*. net.

Cleaning is an operation widely employed in industry. As the introduction to this book points out, it may constitute the major basis of the industry as in laundering; it may be an inherent part of the process by which the finished product is made, as in metal plating; it may safeguard the quality of the finished product, as in the food industry; or it may add to general efficiency, as in plant maintenance. Great technological advances have been made during recent years, and the declared aim of the book is to give a comprehensive treatment of industrial detergency, a subject to which few books have been devoted in their entirety.

A very brief chapter is entitled "The Fundamentals of Detergency". The author admits that this may be a misnomer and that no attempt has been made to discuss the physical chemistry of detergent systems. Other texts need to be studied to obtain a proper understanding of the subject. The chapter on detergent materials is more adequate. Evidence is given to rebut a commonly held belief that the action of synthetic detergents is unaffected by water hardness, and it is emphasized that not all surface-active compounds are detergents. Examples of commercial products are restricted mainly to those of American manufacture.

All cleaning operations must be designed according to the characteristics of the substrate being cleaned, and therefore classification according to industry has been adopted, seven authors contributing to this section of the book. Because of this, some overlapping has occurred, for example, in the chapters on detergent materials and the laundry industry. The latter chapter deals almost exclusively with practice in the United States. The advantages of including a controlled amount of water in dry-cleaning baths are becoming more and more appreciated, and some discussion is given of the theory underlying this addition, although I do not agree that dirt redeposition is adversely affected by the presence of limited amounts of adsorbed moisture on wool in certain detergent systems.

Subsequent chapters deal with detergency in the textile and food industries. Little is known of the effect on man of the ingestion of small quantities of detergents over a prolonged period, and it is therefore appropriate to emphasize the importance of thoroughly rinsing away detergents, so that subsequent contamination of foodstuffs prepared in plant cleaned by them does not occur. Much that is said in the individual chapters on foods and beverages, the dairy industry and dish-washing applies equally to all these applications and could more conveniently have been dealt with under one main heading. The final chapters are devoted to the metals industries and to general industrial cleaning, which covers a range of applications from simple floor-cleaning to the complex treatment of aircraft.

One of the problems in any application of detergents is the selection of those products which are most suitable for the purpose. The evaluation of detergents is not dealt with for every application described in the book, and although the information is available elsewhere, its inclusion would be appropriate in a comprehensive manual of this nature. Nevertheless, the book contains a great deal of useful information concerning American methods in a wide range of cleaning processes. R. E. Wagg

ORGANIC REACTIONS

Organic Reactions

Edited by Roger Adams, A. H. Blatt, Arthur C. Cope, David Y. Curtin, Frank C. McGrew and Carl Niemann. Vol. 7; pp. viii+440; 72*s*. net. Vol. 8; pp. viii+437; 96*s*. net.
(New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953–54.)

Each of the volumes in this series consists of a number of chapters, dealing severally with a single reaction capable of wide application, or sometimes even with a particular phase of such a reaction. The series was begun in 1942, and from its inception it has progressed under the wise direction of Prof. Roger Adams as editor-in-chief, assisted by changing teams of skilled and experienced collaborators.

These successive volumes provide a welcome aid to the practising organic chemist, having his habitation in these latter days in the midst of a deep and rapid river of literature which threatens to rise and engulf him. The life-line of "Beilstein" and similar publications so often falls short of his needs that supplementary devices have become essential if he is to keep his head above water. In other words, the practitioner of organic chemistry needs something that will enable him to make a quick, comprehensive and up-to-date survey of the current position in his particular field of work. "Organic Reactions" renders this kind of service by assembling the requisite information under the heads of specific reactions of outstanding importance, thereby bringing about a dissection of a vast body of published material into manageable units. Experience has shown the great practical value of this method of classification, although, of course, it cannot be claimed to meet every need.

The limited goal of each chapter renders possible a surprisingly thorough coverage of the material and publications concerned. Chapter 6 in Vol. 8, on the metalation reactions with organolithium compounds, may be taken as a typical example. A section of forty-seven pages includes an introduction followed by concise accounts of the mechanism and scope of the reaction. Other types of metalating agents are then mentioned; and details of experimental conditions and procedures are followed by a tabulated summary of such reactions to be found in the literature up to the end of 1952, the yield and literature reference for each of a couple of hundred compounds being given. The seven chapters of Vol. 7 include, among others, the Pechmann reaction, the Skraup synthesis, the von Braun cyanogen bromide reaction, and the epoxidation and hydroxylation of ethylenic compounds with organic peracids. Vol. 8 contains eight chapters, including catalytic hydrogenation of esters to alcohols, the Sommelet reaction, the metalation reaction with organolithium compounds, and β-lactones.

Some of the cathedrals and other noble buildings in Britain enjoy partial relief from their burdens through the activities of associations of 'friends': Prof. Adams and his collaborators, fulfilling a similar beneficent function for molecular edifices, might well be hailed as 'friends of organic chemistry'.

JOHN READ

NEW METHODS OF SCHOOL TEACHING IN AUSTRALIA

Teacher, Pupil, and Task

Elements of Social Psychology applied to Education. Edited by O. A. Oeser. Pp. xiii+196. (London: Tavistock Publications, Ltd., 1955.) 18*s.* net.

IN 1953 a refresher course for teachers, carried out by the method of group discussion, was held at the University of Melbourne, and fourteen contributors to this book, all of them teachers in the University or in training colleges, were leaders of these discussions and have prepared the book in response to a demand by the teachers for a reference manual. The editor, O. A. Oeser, who also contributes two chapters, is professor of psychology at Melbourne.

It would seem that the teachers might have profited by a longer and more thorough treatment of the topics discussed—although suggestions are given for further reading. As it is, the separate sections of the book differ considerably in method of treatment, and in general satisfactoriness. The chapters on testing and on examinations are simple and straightforward; but they are not sufficiently detailed, and neither is that on vocational and educational guidance. The chapter on 'the problem child' is as adequate as is possible in covering such a complex subject in a small space.

But the most interesting and most controversial part of the book deals with the promotion of good social relations between staff and pupils, and of the pupils with each other. It is recommended that the natural social affinities of the children should be assessed by Moreno's sociometric technique; that classes should be divided up into small groups, on the basis of these affinities and of similar ability; and that the groups should carry out their school work as a group activity, with the teacher suggesting and guiding rather than giving direct instruction. Now the suggested method undoubtedly offers points of great interest; and it seems possible that it does promote highly desirable easy and friendly social relations. It is also claimed to make the children more active and more interested, and to stimulate them to work better. But little evidence is available to substantiate this claim.

It seems unlikely that the more intelligent children would profit by these methods in studying the more arduous and difficult subjects. Indeed, the result might be to produce the type of individual described in American society by David Riesman in "The Lonely Crowd": the individual whose sole purpose it is to get on well with others, to adapt his behaviour flexibly to his society, and to do what is expected of him by others. Perhaps the authors have no such intention. But it would be disastrous if such procedures were adopted uncritically, without further experimental test, to the neglect of the intelligent and highly individualistic child, whose particular interests and initiative require individual encouragement and strenuous adult teaching.

SOCIAL ANALYSIS OF LIFE IN A MENTAL HOSPITAL

The Mental Hospital

A Study of Institutional Participation in Psychiatric Illness and Treatment. By Dr. Alfred H. Stanton and Dr. Morris S. Schwartz. Pp. xx+492. (London: Tavistock Publications, Ltd., 1954.) 35*s.* net.

DURING the past ten years American sociologists and social psychologists have shown great interest in the analysis of subordinate institutions within their society and, in particular, in studies of prison and of mental-hospital communities. This focus of attention has been influenced no doubt by contemporary events, which have directed attention to the overcrowded State prisons and State hospitals as social problems of some urgency. In the latter case, the quickening of theoretical interest has been due in no small measure to a series of papers by A. H. Stanton and M. S. Schwartz which began to appear in 1949. The three-year study of the functioning of a mental-hospital ward, on which these reports were based, is the subject of this book.

If there is one generalization which can be safely made about any human institution, it is that it is not perfect. Social analysts, like psycho-analysts, find it easier to recognize failures of function than to do justice to systems which work smoothly. The great merit of this work is that it subjects to careful scrutiny all those aspects of mental-hospital life (such as the formal administration, the daily interactions among patients and between patients and personnel) which tend to be taken for granted and ignored. In repeated instances, the authors have demonstrated that patients' illnesses can be aggravated or relieved in response to events occurring in this social penumbra. Their discoveries are often too true to be altogether welcome. Already they have provoked reactions from incensed administrative psychiatrists; but the data and their interpretations remain, to be confirmed or modified by other social scientists.

Two criticisms may legitimately be directed against this work. First, it is disappointing that original explanatory concepts are so rare; most are derived from established inter-personal theory, and the most original of all (the effect upon a patient's mental state of covert disagreement between two of those in charge of him) now appears to be attributable to previous observations by Suzurek. Secondly, with some notable exceptions, there are all too few instances where the *verstehende* concept (an intellectually satisfying explanation) has been confirmed by systematic, statistically significant, observations. This defect is in part a measure of the pioneering quality of the authors' work, and can be remedied. A valuable section of the book, which will interest everyone concerned with mental-hospital practice, is the review of recent sociological studies in this field.

G. M. CARSTAIRS

ORGANIZATION OF DEFENCE RESEARCH IN BRITAIN

By CHAPMAN PINCHER

THE organization of defence planning in Britain has undergone a revolution since the beginning of the Second World War. Whereas scientists were previously regarded with some suspicion by fighting men as being usually impracticable dreamers, defensive planning is now dominated by scientific thought and methods.

This change would have been inevitable following the emergence of nuclear bombs, guided missiles and other extremely intricate devices; but Britain got off to a good start in post-war defensive thinking because the formulation of policy was already being guided by scientists. This was largely due to the efforts of a few pioneers like Sir Henry Tizard, whose foresight resulted in such war-winning devices as radar.

The present system dates from the establishment of the Defence Research Policy Committee under Tizard in 1946. This Committee dominates the picture and must be considered in some detail.

The Committee is responsible to the Minister of Defence. It consists of fourteen men, the permanent chairman, the Deputy Chief of Naval Staff, Deputy Chief of the Imperial General Staff, Deputy Chief of Air Staff, Deputy Controller (Research and Development) Admiralty, Scientific Adviser to the Army Council, Scientific Adviser to the Air Ministry, Chief of the Royal Naval Scientific Service, Chief Scientist of the Ministry of Supply, Controller of the Navy, Controller of Supplies (Munitions) Ministry of Supply, Controller of Supplies (Air) Ministry of Supply, Controller of Guided Weapons and Electronics, Ministry of Supply, and Secretary of the Department of Scientific and Industrial Research (see p. 260).

A special subcommittee deals with atomic matters and co-opts experts such as Sir William Penney. Special *ad hoc* panels are occasionally set up to take advantage of specialist brains in the universities and in industry.

Since August 1954 the chairman has been Sir Frederick Brundrett, who previously served as deputy to Sir Henry Tizard. Sir Frederick is also scientific adviser to the Minister of Defence and with the additional influence of membership of several other committees is currently the commanding figure in the defence research field.

The Defence Research Policy Committee is purely advisory and has no executive powers; but once its conclusions are approved by the Chiefs of Staff and Minister of Defence, they cannot be changed without the Committee's further agreement.

The cycle of events begins with the formulation of weapons *requirements* by the Chiefs of the separate Services. The Service officers who are responsible for the formulation of requirements are the Deputy Chiefs who are members of the Committee. At this stage these men have a general idea of the performance they want in new weapons and are guided in keeping the requirements within the bounds of practicability by the individual scientific advisers attached to their staffs. It will be noticed that the scientific advisers to the Army Council, Air Ministry and Admiralty (the Deputy Controller (Research and Development)) also figure on the Defence Research Policy Committee.

The Staff requirements are then passed to the Controllers in the Supply Ministry, in the case of the Army, Royal Air Force and Naval Air Services. The general Naval requirements are passed to the Controller Admiralty. (Again it will be seen that these four men also sit on the Defence Research Policy Committee.)

In the Ministry of Supply and Admiralty scientists examine the research and development problems raised by the requirements to consider how they can be met with available resources. They study the questions of man-power, materials, research equipment and techniques. Their considered opinion then goes back to the Service Chiefs who originally formulated the requirements.

It is at this stage that the requirements, by this time usually modified in the light of the opinions already passed to them, are considered by the Defence Research Policy Committee, which it will be seen contains the officers in the several departments who hold executive responsibility for the various aspects of the work. The Committee's prime function is to ensure that the whole defence programme is kept within the limits of the country's resources and finance and that there is no unnecessary overlapping of research effort between the Services. The Service demands are invariably well in excess of possibilities, and the Defence Research Policy Committee does the pruning.

The Committee normally meets once a fortnight. The agenda has been fixed and there is a firm rule that the members must have been notified at least a week in advance of every item to be discussed. This means that the members have had ample time to consider the subjects before the meeting begins.

To do its preliminary work the Committee has a small staff which is carefully selected both from the point of view of ability and security.

There is a full-time staff consisting of a Forces representative and a scientist from each Service with an administrative under-secretary from the Defence Ministry. The Defence Research Policy Committee appoints a scientist to act as the chairman of this full-time staff annually.

In addition there is a part-time staff which is entirely scientific consisting of one representative from each Service, the Ministry of Supply and the Naval Scientific Service. These men remain in their normal posts but devote about half their time to Defence Research Policy Committee work.

The men chosen for these staffs must have special aptitude for viewing the nation's defence problems as a whole without being unduly biased by loyalty to their particular Service.

The Defence Research Policy Committee gets guidance on strategic policy in the form of directives from the Staff Chiefs and the Minister of Defence, which enable it to assign inter-service priorities for those requirements and projects which are considered feasible.

These priorities are, of course, in general terms. Final decisions on precise priorities in individual experimental establishments must necessarily be taken by the supply Ministries, which know the day-to-day situation concerning facilities.

When agreement has been reached by the Defence Research Policy Committee and the resulting programme approved by the Chiefs of Staff and Minister of Defence, executive action is put in hand by the Ministry of Supply or the Admiralty. The work is then begun at one of the Government experimental establishments, or is farmed out to industry.

These Government establishments are numerous and employ several thousand scientists and engineers. Among the best known are the Royal Aircraft Establishment at Farnborough, Hants, the Telecommunications Research Establishments, Malvern, the Fighting Vehicles Establishment at Chobham, the Microbiological Research Department and Chemical Defence Research Establishment at Porton, the Admiralty Signal and Radar Establishment at Portsmouth, and the Admiralty Research Laboratory at Teddington. Atomic weapons research requirements are passed from the Ministry of Supply to the Atomic Weapons Research Establishments of the Atomic Energy Authority at Aldermaston, Berks.

Many industrial firms have set up substantial departments and in some cases entire factories for defence research and development.

Through its staff which visits the experimental establishments and industrial concerns involved, the Defence Research Policy Committee is kept informed on how projects are progressing. From time to time projects have to be modified or occasionally scrapped because they are not working out according to plan, have been made obsolete by events or for economy reasons.

The duties of the Committee so far described deal with clear-cut applied research. There is a special Research Sub-committee which concerns itself to ensure that the more nearly fundamental research for defence purposes carried out in Government establishments is kept on what appear to be the most profitable lines. Clearly even in fundamental research carried out with public funds, limits have to be set much more closely than in the universities.

It will be seen that the Committee does not usually initiate projects, but functions mainly by modifying the proposals of others. Nevertheless, it does exert considerable influence on future projects through its annual report called the Defence Research Policy Review, which is, of course, a highly secret document. The first part of the review is a progress report, but Part 2 is a "Way Ahead" section dealing with future requirements.

For such wide strategic surveys the Committee needs to be informed on some aspects of foreign weapons developments. This information is supplied by the Staff working in the Defence Ministry which controls the Joint Intelligence Bureau (see *Nature* of March 26, 1955).

The Committee looks into special fields two or three times a year to produce detailed reports on such subjects as guided missiles, radar, and signals communications. It also examines and co-ordinates draft annual estimates on research and development submitted to the Ministry of Defence by the Admiralty and Ministry of Supply.

The views of the Committee are continually made known to the Cabinet by the Defence Minister, who is kept advised of the Committee's activities through the chairman. As pointed out in *Nature* of January 7, p. 18, the Defence Minister has been given responsibility for framing general policy governing research and development. In this connexion he relies heavily on the chairman of the Defence Research Policy Committee, who is also his personal scientific adviser.

Not only is the chairman in constant touch with the Defence Minister but he is also occasionally invited to sit in at meetings of the Cabinet's Defence Committee. In addition, he is in regular touch with the Chiefs of Staff and frequently attends meetings of their Committee, which now has a permanent chairman (Sir William Dickson) based in the Ministry of Defence.

Thus the chairman of the Defence Research Policy Committee is able to ensure that its members are in turn kept aware of the Government policy which must overshadow all defence planning.

AUTOMATIC CONTROL IN THE PROCESS INDUSTRIES

MUCH attention has been directed recently to the potentialities of automatic control as a means of increasing industrial efficiency, particularly by the use of electronic measuring and control equipment and, above all, by employing electronic computers. Rapid advance towards the completely automatic factory has been predicted and serious misgivings have been raised about the social consequences of employing more and more automatic equipment in place of men to control factory operations.

Consideration of the completely automatic factory and its implications for society as a whole can, however, safely be confined for the time being to the light engineering industries, in which the mass production of components is carried out by machines on a production line. The automatic control of such production lines has already been highly developed in specific cases and will, no doubt, be extended rapidly in the near future. In the process industries, however, a completely automatic factory is still a long way off and, if it ever comes into existence at all, it will be based on a steady evolution of technique rather than on spectacular revolutionary advances. Individual sections of, say, oil refineries or chemical works are at present automatically controlled to a large extent. They could not in many instances be successfully operated without their automatic control systems; but on the other hand they still demand the presence of human operators to reset the automatic controllers to meet the needs of changing conditions.

The process industries have been steadily developing and applying automatic control over the past thirty years, and the number of operators employed is consequently already small. Economies in operation, due to improved automatic control systems, will not result in general from the decrease of this small number of operators but rather from improved efficiency of operation. The problems to be overcome in the further development of automatic control in the process industries are, therefore, purely technical and unlikely to involve questions arising from redundancy of operators.

The object of the very considerable amount of research and development being carried out in the field of process control is to make available the full potential of automatic control to decrease production costs. This object can only be achieved by taking account of the requirements of the control system when the process and plant are being designed. To do this, the designer must be able to calculate the characteristics of the process and plant, and to predict the effect of modifications to their design on all aspects of operation—including control. This must require a quantitative knowledge of those characteristics of process and plant which determine their controllability.

It is self-evident that when a control system has to take action, it must either correct a disturbance in conditions or effect a desired change in them. Thus, to design and adjust a control system it is necessary to know how the plant and process respond to changing conditions; that is to say, it is necessary to know the 'dynamic' characteristics of plant and process as well as their characteristics in steady conditions.

The development of automatic control techniques in the process industries has been very severely hampered by lack of knowledge of these dynamic characteristics. Until they can be calculated, control systems cannot be designed quantitatively. In related fields, such as the design of electrical amplifiers or of servo-systems to control machines, a much more quantitative approach to control system design is possible because the dynamic characteristics of the controlled system itself can be calculated with much more accuracy.

Since 1946 there has been a noticeably increasing emphasis, in the papers written on process control, on the necessity for studying the dynamic characteristics of processes and plant, and for enlisting the assistance of all concerned with their design and operation in obtaining the data required, by experiments on the factory.

The engineers responsible for the development and design of processes, and the engineers responsible for the design of their control systems, have a common interest in obtaining these data and in collaborating to develop the technique of process control system design. They must also collaborate closely with those responsible for operating process plant, on which the necessary experiments to obtain data must be carried out. The plant designer, who is often a chemical engineer, must play a vital part because he will have the responsibility of incorporating in the plant the design features which these investigations will show to be desirable for improving controllability.

The importance of close collaboration between the engineers concerned with the design and operation of processes and plants and the control system designers has been stressed repeatedly during the past few years. The most recent and authoritative statement on this subject was made by Sir Harold Hartley in April 1955, in his presidential address to the Institution of Chemical Engineers. In this address the problem is clearly stated as follows:

"In the chemical and process industries, the whole tendency is towards continuous plants with the economies they offer in capital cost, man-power and throughput—whenever the volume of production is sufficiently great. Such continuous plants have demanded a large amount of instrumentation and automatic control and one of the main purposes of a pilot plant is to investigate the instrumentation required. In many cases the plants have been designed and the instruments and control added later, and in fact all processes are really manually controlled because every major load change in general requires re-setting of the desired values of all the controls. Electronic devices are much quicker and more accurate than the human senses, and with appropriate servo-mechanisms they offer great advantages. With the rapid advances in the design of automatic controls, design engineers have been able to make considerable improvements by the incorporation of the latest standard instruments as they come on the market. Recently this approach to the process design problem, the addition of controls to process flow sheets, has reached something of a stalemate. It is now clear that the major advances will only be achieved if the use of automatic control is considered in the earliest design stages. This means that there must be consultations between the chemical engineer and the automatic control engineer from the earliest stages and a sympathetic understanding between them.

"We must move on from the stage of adding process controls in an empirical manner. This is not an easy matter, however, and it will call for a basically new approach to the problem of process design. Two difficulties appear to stand out. First there is a grave shortage of automatic control engineers with the necessary experience. Coupled with this is the shortage of chemical engineers with sufficient understanding of the theoretical approach to automatic control. Secondly, there is an almost complete lack of the information on plant and process characteristics which is required to enable automatic controls to be applied in a scientific way. Thus we have to face a dual problem of education and training on the one side and lack of quantitative data on the other."

Some six months earlier, Sir Harold had proposed a joint conference between the Institution of Chemical Engineers and the Society of Instrument Technology—the membership of which includes the majority of those actively interested in developing and applying automatic control in the process industries. This proposal was welcomed by the Institution and the Society alike as a means of attacking the "dual problem of education . . . and lack of quantitative data".

The need for the conference was very clearly demonstrated by the attendance of about eight hundred engineers, physicists and mathematicians at Church House, Westminster, on October 4, when the proposed conference was held. Both the size of the attendance and the very representative cross-section of engineering interests it represented afforded clear proof of the interest in the subject of discussion, namely, "Automatic Control in the Process Industries".

The first object of the Conference was defined in the following words by Mr. John Oriel, president of the Institution of Chemical Engineers, in his opening address. "The time has passed when instrumentation could be looked upon as a luxury; nowadays, with much of our plant designed for continuous operation, often with high throughput and with very severe operating conditions, the control is an essential part of the process itself, and the design of the plant is incomplete unless full account has been taken of the instrumentation. The need, therefore, for the closest collaboration between the instrument technologist and the chemical engineer during the design, development and operation stages is of the greatest importance. The need for a complete understanding of each other's problems cannot be over-estimated." Mr. Oriel thus placed the emphasis firmly on the need for close collaboration between those who develop and design control systems and those who develop and design processes and plant, and the necessary basis for such collaboration is stated unambiguously; namely, "a complete understanding of each other's problems".

The Conference was therefore essentially educative and the papers were carefully arranged to give as concisely as possible, and in the simplest terms, the basic information required by the chemical engineer to enable him to appreciate the requirements of the control system when designing processes and plants, and the necessity of carrying out investigations on full-scale plant in order to obtain information about the mechanism governing its behaviour as part of the control system.

It may well be asked at this stage why the chemical engineer has not become familiar with the basic principles of automatic control during his academic training, and why he cannot supply the information about his processes and plants which is required by the control system designer. These two questions must therefore be answered; but first it must be emphasized that the real significance and importance of this Conference rests on the fact that it marks the recognition of the problem which the questions pose, and represents the first step in a combined attempt by the plant designers and control system designers to solve it.

Education of the Chemical Engineer in Control System Design

The education of the chemical engineer is not complete unless he has a knowledge of the basic principles underlying the proper application of instrumentation and automatic control to industrial processes and plant, because, as has been stated already, their design and their method of operation have become (and will become increasingly) dependent for their economic success on their controllability. The universities and technical colleges have recognized the desirability of providing the chemical engineer with a knowledge of these basic principles, and the chemical engineering departments of several universities have made a generous allowance in their teaching programmes for a study of control systems. The very wide field to be covered in a chemical engineering syllabus makes this difficult to do; and it has been found possible to do it only in those schools which have appreciated the vital importance of the subject and are prepared to sacrifice something else for it. Many even of the younger chemical engineering graduates have had little opportunity, therefore, of studying the subject during their undergraduate years, and it was for these graduates and for those who graduated before instrumentation had achieved the general appreciation it now enjoys that the Conference was arranged.

As time goes on, and the inclusion of substantial courses on automatic control in graduate engineering syllabuses becomes more general, the need for joint conferences of plant and process designers and control system designers will certainly increase. Future conferences will not be primarily educative as in the case of this first conference; they will be pitched at an increasingly advanced technical level and will be concerned with the discussion of system design problems.

Chemical Engineering Data

The available chemical engineering data, although not as accurate as is sometimes desirable, are in general adequate to permit the prediction of process and plant behaviour in steady conditions and, therefore, to permit the economic design of plant to give a specified output of a given product of the required quality—as long as there are no major disturbances to the operating conditions. It is, of course, the object of a control system to eliminate such disturbances or to minimize their effect on operation but it will be clear that if they are to do so most effectively, the dynamic characteristics of the process and of the plant must be designed to make the task as easy as possible. Such design, however, demands a knowledge of the mechanism governing these characteristics, and since this mechanism has not been of immediate concern to the plant designer in his main activity of designing for a steady output he cannot be blamed for not having studied it. In future, however, he must. The essential basis for such study was presented very concisely and simply in the first two papers presented at the Conference

It is not proposed to give a summary of these and other papers presented at the Conference and the discussion upon them because they have been published in full in the *Journal of the Institution of Chemical Engineers*.

Economics

It is of interest, however, to record the very significant fact that in every paper, including the opening address by the president of the Institution and the concluding remarks by Sir Harold Hartley, past president of the Institution, and by the president of the Society of Instrument Technology, the economic aspect of control system design was emphasized. Even in the first paper dealing with fundamental principles. Mr. R. S. Medlock pointed out that the design of a control system depends on the economics of the process, and increasing emphasis was placed on the economic aspect of the problem by each succeeding paper until the last paper but one, by Mr. S. W. J. Wallis, which was devoted entirely to the economics of process control.

This emphasis on the economics of the matter reflects the growing consciousness of control engineers of their responsibility for developing, and applying to the full, the potential of automatic process control as a means of reducing production costs.

The gradual evolution of process control to its present high standard of performance has been so continuous that, to a large extent, its contribution to reduction of process operating costs has been masked. Mr. G. C. Eltenton, in opening the discussion at the afternoon session, was voicing the conviction of the process control engineers themselves, when he pointed out the value of being able to give firm facts to demonstrate the reduction in production costs which automatic control has effected in specific instances. Unfortunately, it is very rarely that it has been possible to obtain the firm figures which are unanimously agreed to be so desirable, and Mr. Eltenton's remarks presented a challenge to both control and chemical engineers which they must take up. This will result in the production of new figures on the economics of process operation, and these will be of the very greatest importance to the subject—not only as a means of extending the use of automatic control in the process industries, but also as a means of improving the design of process control systems and of process plant as a whole.

Organization

Two other very important matters were raised during the Conference; both concerned organization, in different ways. The first concerned the methods of organizing the design of processes and plant in order to bring to bear on the problem the full knowledge available to both the chemical engineer and the control engineer. In opening the discussion following the morning session, Mr. J. E. Braham directed attention to the difficulties involved in this problem, and to the necessity of giving thought to their solution at the present time. Clearly this is very necessary, because much delay will occur in the application of new design practices unless the process industries have built up design organizations of the proper nature to deal with them.

The organizational problem associated with the new conception of combined design by the chemical engineer and the control engineer had received too little previous consideration to permit any immediate discussion at the Conference, but there is no doubt that Mr. Braham's timely warning of the difficulties to be overcome will be the subject of considerable attention in the near future.

The second organizational problem arises from the necessity of building up a fund of experimental data on plant and process characteristics. These data should clearly be collected and correlated, as Mr. Oriel pointed out in his opening address, by some central body "where there can be a ready exchange of data which is so urgently needed" by both the plant designer and the control designer.

Sir Harold Hartley, in his summing up of the Conference, suggested that this might well be a function of the National Chemical Engineering Research Station, which it was recommended by the Cremer Report should be set up and sponsored jointly by the Government and industry. Some delay, however, is unavoidable before any new organization could undertake this responsibility, and it was suggested by the president of the Society of Instrument Technology that the Control Section of the Society could well undertake this important work in the meantime. By doing so, the Society could avoid the delay which might otherwise occur in organizing the collection and correlation of the data and could make a valuable contribution to accelerating progress in this field and thereby decrease the production costs of the process industries.

It is clear, however, that the success of any central organization employed for collecting and correlating technical data, or of any organization in individual companies for putting into design practice the new techniques envisaged, must depend on the close collaboration of process plant and control system designers. The most important result of this Conference has been to stimulate a joint approach to the problem and care must be taken in the future to encourage and preserve it.

AGOSTINO BASSI, 1773–1856

By Dr. G. C. AINSWORTH

Department of Botany, University of Exeter

THE concept of pathogenicity is now so familiar that it seems scarcely possible that less than a century ago the question of the reality of microbial infections could still be a living issue. The controversy which then prevailed was, however, at least for pathogenic fungi, becoming a rearguard action by the few who were unable to appreciate the significance of discoveries made between 1835 and 1846 by an Italian lawyer turned farmer, by a Hungarian medical man in Paris, and by an English country clergyman—microbiologists then, as now, being drawn from diverse disciplines.

The Rev. Miles Joseph Berkeley's classical paper of 1846[1], "Observations, botanical and physiological, on the potato murrain", in which he concluded of potato blight that "the decay is the consequence of the presence of the mould and not the mould of the decay", has long been accepted as a landmark in the history of plant pathology. David Gruby's series of six short papers[2] published between 1841 and 1843, in which he elucidated the mycotic nature of thrush and the principal types of ringworm in man, is generally recognized to have laid a firm foundation for the development of medical mycology. Agostino Bassi (Fig. 1), the centenary of whose death falls on February 15, who was the first to elucidate the etiology of a contagious microbial disease and to effect the experimental infection of one living organism by another, has, on the other hand, been neglected outside his native country. He receives a few words in most histories of biology but he has been largely forgotten, even by mycologists who have perpetuated his name in the specific epithet of one of the common entomogenous fungi.

Agostino Bassi's life was uneventful and can be quickly summarized. He was born in Lombardy on September 23, 1773, at Mairago, four miles from Lodi, where he went to school. Then he studied law at the University of Pavia and after graduating in 1798 was appointed to the post of provincial administrator and assessor at Lodi, later becoming an official under the new Napoleonic regime. Like so many men of genius, Bassi suffered from life-long ill health. Defective eyesight forced him to relinquish office and to retire to his father's farm at Mairago, and one result of this was the publication in 1812 of his first book, "Il pastore bene istruito" ("The Well-educated Shepherd"), a comprehensive work of 460 pages on sheep farming. In 1815 an improvement in his health allowed him to re-enter government service, but only for a year, after which he returned to Mairago, where he devoted himself to agricultural and scientific pursuits until his death in 1856. At first financially embarrassed, Bassi in 1838 inherited a fortune from a cousin, a poor tailor of Mairago who became a wealthy military contractor and was created Count of Sommariva by Napoleon.

Bassi's interests were wide, and, while at the university, in addition to his legal studies, he took courses on mathematics, medicine and various aspects

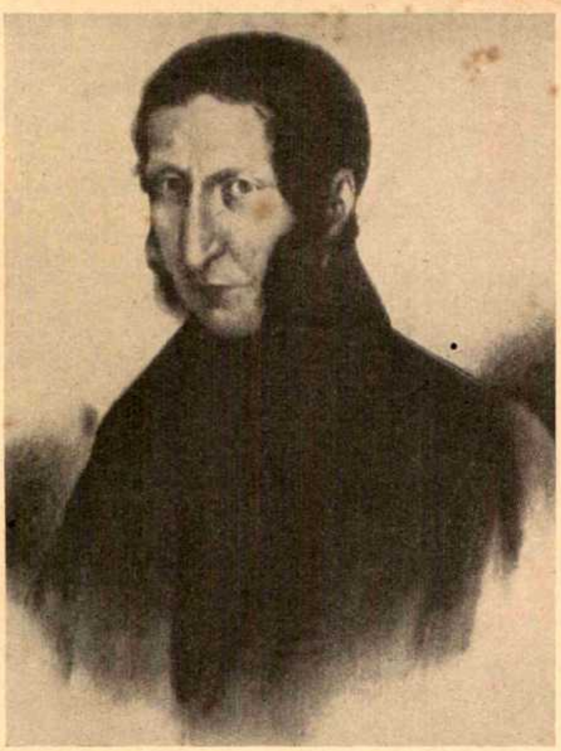


Fig. 1. Agostino Bassi (1773–1856)

of natural science, his teachers including the anatomist Scarpa, the physicist Volta, and Lazzaro Spallanzani[3] (1729–99), the versatile physiologist noted for his studies on spontaneous generation which antedated by a century those by Pasteur and Tyndall. Bassi was also of an inquiring turn of mind and in 1807 he decided to investigate the dread muscardine disease of silkworms which ravaged the silkworm industries of Italy and France. The notion prevailed that the cause of muscardine was 'environmental', that is, was due to the state of the atmosphere, the food, or the method of breeding, and it was to these aspects that Bassi first turned his attention. He "bred silkworms in all ways, subjecting them even to the most barbarous treatment ; the poor creatures died by thousands and in a thousand ways", but not a single case of muscardine disease resulted. He next tested the hypothesis that the disease was due to hyperacidity and studied the effects of phosphoric acid, but although the silkworms again died there was only putrefaction ; no hardening of the corpse and no white bloom on its surface, the characteristic post-mortem signs of muscardine disease. Bassi was able to simulate death by muscardine disease by hanging up silkworms enclosed in paper bags in a chimney over a continuous fire and then placing the hardened corpses in a cellar or keeping them moistened with water. Silkworms so treated deceived the experts, but to Bassi's chagrin they lacked the one essential character of a silkworm which has died from muscardine disease. The "contagious faculty" was missing. They did not induce the disease when placed among healthy silkworms.

Discouraged by his failure, Bassi was "humiliated in the extreme, silent and idle" and "oppressed by a terrible melancholy" for many months ; but in 1816 his spirits revived and he began work again on a new line of attack suggested by his observations on the course of natural epidemic outbreaks. It occurred to him that the disease did not originate spontaneously but was caused by an "extraneous germ". He soon discovered that the infectious material was the white efflorescence which developed on the dead silkworms, and by subjecting this material to microscopic examination (Bassi possessed a compound microscope which after his death was acquired by the town of Lodi ; Berkeley worked with doublets until 1868), he found it to be "a plant of the cryptogamic kind, a parasitic fungus". By a long series of comprehensive and often elegant experiments Bassi was able to demonstrate that this fungus was the pathogen. He showed that silkworms of all ages were susceptible and that an infected worm became infectious only after "calcination"—the sporulation of the fungus over the surface of the dead larva—and he concluded that every "spontaneous" outbreak of the disease could be traced to the introduction of infected silkworms or to the use of contaminated cages or utensils. He also developed measures by which the disease could be controlled.

By 1833 Bassi felt ready to submit his work for adjudication by the University of Pavia, and in 1834 he performed a series of the crucial experiments before a commission of nine professors from the Faculties of Medicine and Philosophy. The professors were convinced. They issued Bassi with a signed certificate which he printed in the preface of the first part of the monograph ("Del Mal del Segno, Calcinaccio o Moscardino" ; Parte Prima : "Teoria", 1835 ; Parte Seconda : "Pratica", 1836) (Fig. 2) in which he gave a detailed account of his investigations

and his conclusions. This work aroused much interest but was given a mixed reception. Giuseppe Balsamo Crivelli, professor of natural history in the University of Milan, studied the causal fungus and named it *Botrytis bassiana* (now *Beauveria bassiana*), and confirmation of Bassi's findings was published in 1838 by the director of the Paris Natural History Museum, Victor Audouin, to whom Bassi had sent a copy of his monograph and an infected chrysalis. There were opponents, to whose opinions Bassi was perhaps unduly sensitive, but his results were well founded and convinced the unprejudiced.

The study of muscardine disease is Bassi's major achievement. In the years that followed, he issued a second edition of "Del Mal del Segno" (1837) and published additional observations on this disease. He also wrote lengthily on pellagra and cholera, on diseases of the mulberry, vine and potato, and on other topics. He received a number of honours from both Italian and foreign academies, and to commemorate the centenary of Pasteur's birth a collected edition[4] of Bassi's writings was published in Italy in 1925 under the auspices of a national committee headed by Mussolini. The collected writings are supplemented by biographical data and by a bibliography which lists more than forty articles, all in Italian, bearing on Bassi's life and work. The most important account of Bassi in English is that by Major[5].

As with many other outstanding figures in the history of science, Bassi crystallized ideas which were becoming prevalent. The influence on Bassi of Spallanzani's views on spontaneous generation has already been implied, and Bassi must have been familiar with the frequent association of fungi with decay and disease. In England an illustrated observation on salmon disease of freshwater fish had been given as early as 1748, and in 1832 the zoologist, Richard Owen, when dissecting a flamingo which had died at the London Zoo, found the lungs lined with a vegetable mould and concluded that there were Entophyta as well as Entozoa. The trail became even warmer when, as cited by Bassi, Profs. Configliachi and Brugnatelli, of Pavia, suggested that the muscardine disease had a mycotic origin because of the fungus smell associated with silkworms killed by this disease; but to Bassi must go the credit of being more perceptive and persevering than his contemporaries. Bassi's work was in its turn the stimulus that led Schoenlein to discover the mycotic nature of favus in man and it certainly influenced both Gruby and Berkeley; the latter including in his paper on potato blight the first illustration of *Beauveria bassiana* to be published in Britain.

Bassi, if given to verbosity, was a modest and at times almost diffident writer. He was generous to others but he appears not to have suffered fools gladly, for in the preface to "Del Mal del Segno", while appealing to savants and breeders for their observations, he warns them that "to save time and trouble I shall reply only to those which seem to me sufficiently founded in fact to be able to further in some way the progress of science and art". Bassi lived up to his motto: "Quando il Fatto parla Ragion tace, perchè la Ragione è figlia del Fatto, non il Fatto figlio della Ragione" ("When Fact speaks Reason is silent, because Reason is the child of Fact, not Fact the child of Reason").

I am much indebted to Prof. R. Ciferri, of the University of Pavia for a microfilm of Bassi's monograph, for a portrait of Bassi, and for taking me on a pilgrimage to Lodi, and to Mr. P. J. Yarrow, of the University of Exeter, for translations from the Italian.

OBITUARIES

Dr. Arthur Felix, F.R.S.

THE sudden death of Dr. Arthur Felix on January 14 at the age of sixty-eight removes from the bacteriological world one who had made his home in Britain for nearly thirty years and who had come to occupy, in the niche he carved out for himself, a position of considerable authority. The work he had done, much of it as a young man, had earned for him an international reputation, and it was a source of great joy to himself and his friends when the value of his contributions was recognized in 1943 by his election to the Fellowship of the Royal Society. He was an excellent example of the group of investigators who, trained in the field of chemistry and physics, have turned their attention to bacteriology and added so much to our knowledge of medical science.

Dr. Felix was born of Orthodox Jewish parents on April 3, 1887, in Silesia—now part of Poland—not far from Tarnow. He was educated at a German *Gymnasium*, and then went to Vienna, where he studied chemistry and took his doctorate. After a period of two years or so learning mycology under Lafar, he was called up on the outbreak of war in 1914, and attached to a laboratory in a field ambulance posted near Cracow. There he met Weil, associate professor of bacteriology at Prague, under whom his bacteriological training was begun. The two formed an admirable pair. Between them they observed a peculiar phenomenon that they rapidly adapted to the diagnosis of typhus fever, which was then prevalent on the Eastern front. The Weil–Felix reaction, as it was called, proved of immense value in the differential diagnosis of typhus from typhoid and other fevers of unknown origin, and stimulated a great deal of research to explain why it was possible to obtain a specific agglutination reaction with an organism playing apparently no part in the causation of the disease. Intimately bound up with this reaction was a curious variation observed by Weil and Felix in the behaviour of one of the strains—*Proteus X* 1—which was under some conditions motile and under others non-motile. The association of this change with the serological behaviour of the organism was quickly appreciated, and a distinction established between the loose floccular agglutination dependent on the flagella of the motile form and the compact granular agglutination dependent on the body or somatic substance present in both motile and non-motile forms. These observations on *Proteus* were later found to fit in admirably with similar observations made several years previously by Smith and Reagh in the United States on a member of the *Salmonella* group, and provided the basis of a wide generalization on the antigenic structure of bacteria.

At the end of the First World War, Felix worked for a time at Prague and, after taking a three-months course in tropical medicine at Hamburg, moved in 1920 to Palestine, where he served as a hospital bacteriologist for some years. In spite of his attachment to Zionism, he was forced to the conclusion that Palestine could not offer him the opportunities for research that he wanted, and he gladly accepted an offer in 1927 by Prof. J. C. G. Ledingham to join the Lister Institute in London. There he settled down among congenial colleagues and added to his reputation by discovering the *Vi* antigen of the typhoid bacillus. In 1939 he was appointed to a post in the Emergency Public Health Laboratory Service, in which he built up what was later to become the Central Enteric Reference Laboratory and Bureau. His development of the *Vi*-phage typing method for 'finger-printing' typhoid bacilli, which had been introduced by Craigie and Yen in 1938, attracted world-wide interest, and in 1947 Felix's laboratory at Colindale was designated the international reference laboratory for the phage-typing of these organisms. Felix retired from the Public Health Laboratory Service in 1954, and returned to the Lister Institute where, with a research grant, he was able to tidy up some of his unfinished work.

Dr. Felix married in 1923 Leah Gluckman, of Tel-Aviv, who survives him. G. S. Wilson

Prof. James Small

Prof. James Small died on November 28 at the age of sixty-six. Born at Brechin, Forfarshire, he was educated at Brechin High School, the Pharmaceutical Society's School, and Birkbeck College (University of London). After graduation he lectured for a brief period at Armstrong (now King's) College, University of Durham, and then at the outbreak of the First World War joined the Black Watch Regiment. He was wounded and invalided out of the Army in 1916, and returned after a period of convalescence to his appointment at Armstrong College. In 1916 he became lecturer in botany at Bedford College, University of London, and in the following year was appointed also lecturer at the Pharmaceutical Society. He left London in 1920 to take the chair of botany in The Queen's University, Belfast, succeeding Prof. R. H. Yapp. He was elected to the membership of the Royal Irish Academy in 1922, and to the fellowship of the Royal Society of Edinburgh in 1926. He held the chair at Belfast until his retirement in 1954, when the Senate of the University bestowed the title of emeritus professor upon him.

Small's first major research was on the Compositae. His work on this family was published as a *New Phytologist* monograph in 1919 under the title "The Origin and Development of the Compositae", and for this research he received the degree of D.Sc. of the University of London. In 1922, Small contributed a chapter to J. C. Willis's book, "Age and Area", on the evolution of the Compositae, and this initiated a series of papers in which he joined Willis in rejecting natural selection as an explanation of the course of evolution, advocating instead the idea of a sudden origin of species. He drew evidence for this from several groups, plant and animal, but particularly from the diatoms and Foraminifera, which have fossil records suitable for quantitative analysis. Recondite in style, these studies on "quantitative evolution" have seemed to some almost perversely out of step with current evolutionary thought; yet by his intensive analysis, Small brought to light quite remarkable regularities in the evolutionary history of the groups that came under his attention, regularities which remain to be explained by any evolutionary theory claiming to have general validity.

His other main line of research concerned *p*H phenomena in plants. He devised a colorimetrical method for the determination of *p*H in plant tissues in the early nineteen-twenties, and the results of numerous observations were brought together in the *Protoplasma* monograph "Hydrogen-ion Concentration in Plant Cells and Tissues" in 1929. His book, "*p*H and Plants", was published in 1947, and another of a more general nature, entitled "Modern Aspects of *p*H", in 1953. In this year also he wrote a contribution on "The *p*H of Plant Cells" to the current series of *Protoplasmatologia* monographs, and during his final illness he completed the correction of the proofs of a contribution on the estimation of *p*H values in living tissues and saps to Paech and Tracey's "Modern Methods of Plant Analysis".

His work on *p*H led Small to an interest in stomatal mechanisms, on which he published several papers. He was also actively concerned with the problems of protoplasmic movement, and devised a technique for its study in living stems. His important observation of very high rates of cyclosis in living sieve-tube elements of marrow is often overlooked, despite its high significance in relation to solute translocation.

Small's many-sided work on evolution and plant physiology was recognized in 1951 by the award of the Makdougall–Brisbane Prize of the Royal Society of Edinburgh, for distinguished research published in the journals of the Society.

His early interest in pharmacognosy was responsible largely for the writing of Small's "Textbook of Botany" (first edition, 1921; fourth edition, 1937), which was intended principally for the use of medical and pharmaceutical students, and which in its encyclopædic nature reflected its author's own vast acquaintance with morphological botany.

For practically a quarter of a century Small was a member of the committee of the British Pharmacopœia, and he served on the council of the Pharmaceutical Society of Northern Ireland from its inception. He wrote innumerable papers on the botanical characteristics of officinal plants, and contributed a long series of beautifully illustrated articles to the journal *Food* on the structure, properties and uses of drugs and spices.

From 1920, when winning a vest-pocket camera in a newspaper competition provided an introduction, Small had an enthusiastic interest in photography, both technical and artistic. He became keenly aware of the potentialities of photography for recording the structures of botanical objects in the magnification range × 1–20, and his superb pictures taken with the Small–Watson camera have been widely published and exhibited. This activity gained him election to the fellowship of the Royal Photographic

Society in 1938—an honour which he treasured as highly as any that came to him in the more academic sphere.

A great lover of argument, Small never failed to stimulate through his perennial heterodoxy, coupled with his impressive width of botanical knowledge. To those who knew him well he was the most kindly and generous of men, full of a humour which was wont to find its expression at times in the gentle teasing of authority, more particularly authority which was itself humourless.

He is survived by his wife, two sons and daughter.

J. Heslop Harrison

Prof. D. R. Boyd

David Runciman Boyd, who died on December 28, gave forty-one years service to university education in Southampton, and was one of the ablest of a very small and steadfast band whose work has made the University of Southampton possible. Born on February 26, 1872, he was the son of the minister of the parish of Mains, near Dundee. His father died when he was only one year old, leaving a widow and three young children in straitened circumstances. The family moved to Edinburgh, and young David attended the then rather spartan John Watson Institution during 1880–86. After a short period on the classical side of George Watson's College, he moved to Glasgow and in 1888 entered the University of Glasgow. He had a distinguished undergraduate career, gaining prizes in chemistry, natural philosophy and mathematics, and in 1892 was awarded the B.Sc. degree with honours in chemistry. With the Robert Donaldson scholarship he studied in Victor Meyer's laboratory at Heidelberg, acting as Jacobson's assistant for a year, and gained the Ph.D. degree. After about two years as demonstrator in chemistry, under Frankland, at the Mason College, Birmingham, he was one of five lecturers appointed in 1896 to the Hartley Institution, Southampton, with the object of bringing the teaching up to university standard. This was so far successful that the Institution became the Hartley University College, with a small and precarious Treasury grant, in 1902. It was largely due to Boyd and his colleague, John Eustice, head of the Engineering Department during 1892–1931, that the College survived the frequent crises of the first decade of this century.

Up to 1919, Boyd never had more than one academic assistant, and the major part of a heavy teaching programme fell on him. He was an exceptionally clear and inspiring teacher: Prof. C. K. Ingold, a student at the College during 1911–13, writes: "he treated us to a most exciting exposition of the whole of Chemistry as a living, growing subject, rich in opportunity for the questing spirit. Werner's resolution of cobaltammines, and Knorr's and Kurt Meyer's work on ethyl acetoacetate came hot from the Annalen or Berichte, yet without sacrifice to the pattern of the lecture course as a whole. Everything was critically (and remarkably soundly) assessed, and some much publicized but unsound work dealt with severely". After 1920, with a somewhat larger staff, though still small by university standards, the teaching was maintained throughout at a very high level until his retirement in 1937.

Until about 1930, Boyd kept research going actively, despite very meagre resources. His name appears on some twenty papers, and another ten by his pupils are on lines initiated by him. He studied various aspects of the chemistry of aromatic compounds, and a series of papers on organic compounds of phosphorus is of particular interest. Two papers on the kinetics of reaction between sodium derivatives of phenols and ethylene oxides are still frequently quoted. He encouraged several other successful lines of research, in different branches of chemistry, in his department. He was awarded the D.Sc. degree of the University of Glasgow in 1902, and frequently examined for that University.

Boyd was invaluable in the administration of the College, in which he took a large part. He was chairman, later dean, of the Faculty of Science for many years, and vice-principal after the retirement of Prof. Eustice in 1931. He was tall, gentle and dignified, with courtly manners; he spoke and wrote clearly and persuasively, and spoke so little of himself that many of his colleagues were unaware that, over several years while holding the chair, he read for the Bar and qualified as a barrister of the Inner Temple. His unvarying maintenance of high academic standards, unselfishness and outstanding integrity earned the confidence of his colleagues; and he was much loved and respected in his own department. He married in 1909, and had two sons; but his later years were saddened by the death of both his sons in 1944 on war service, and his wife died last August. What the University of Southampton owes to him cannot be over-estimated; and he rendered notable services to chemistry both through his own researches and by the inspiration and sound training he gave to many generations of pupils, whose collective contributions to research and to teaching are an imposing monument to their teacher.

N. K. Adam

Prof. P. N. Chirvinsky

Petr Nikolaevich Chirvinsky was born on February 7, 1880, in Moscow in a family of a scientific worker. In 1902 he graduated from the University of Kiev. In 1909 he was appointed professor of applied geology in the Don Polytechnical Institute at Novocherkassk and finally in 1943 he became professor of petrology in the University of Molotov (formerly Perm). He died on June 21, 1955.

A petrologist and mineralogist by profession, Chirvinsky took all allied sciences as his province. In his fifty-three years of academic life, it is estimated that he published 380 papers and books comprising 6,760 printed pages, and covering such varied subjects as petrology, mineralogy, crystallography, meteoritics, geology, hydrogeology, astronomy, physics, chemistry and geochemistry. Of these the first four were his main preoccupation, and he has to his credit many published descriptions of igneous, metamorphic and sedimentary rocks, minerals and meteorites. He was particularly interested in the mineral composition of granites and other igneous rocks, and in this connexion he elaborated a method of "geometrical–chemical" analysis (1937) and published a book on the average composition of rock-forming minerals (1953). Another interest was the chemical composition and genesis of minerals, and one of his papers on a uranium mineral was published in English (*Miner. Mag.*, 20, 287; 1925). More than eighty papers and notes were devoted to meteorites. He was also very much alive to the wider problems of cosmology and geochemistry. He was a modest and friendly man, and an excellent and inspiring teacher.

S. I. Tomkeieff

NEWS and VIEWS

The Department of Scientific and Industrial Research :

Sir Ben Lockspeiser, K.C.B., F.R.S.

In March of this year Sir Ben Lockspeiser ceases to be secretary to the Committee of the Privy Council for Scientific and Industrial Research. He was appointed in 1949, and has, therefore, had the responsibility of guiding the largest of the Government's Research Councils through a most important phase of its development. When he took over, D.S.I.R.'s recurrent expenditure was little more than £3 million, and its capital grant about £100,000. To-day the first runs at £6·5 million, while the second stands at £1·3 million. In parallel, D.S.I.R.'s scientific staff has increased from 1,700 to 2,400. Sir Ben was ideally suited to bring about this expansion. He brought to his task considerable administrative capacity and experience, and a life-long knowledge of Government scientific establishments. From 1920 until 1939, when he became assistant director of scientific research at the Air Ministry, he was a member of the Royal Aircraft Establishment, Farnborough, and before moving to D.S.I.R., he was successively director-general of scientific research, Ministry of Aircraft Production, and chief scientist to the Ministry of Supply. During the period of his forceful reign, Sir Ben has constantly kept to the fore the conception of D.S.I.R. as an agency which is concerned not only in the cultivation of new scientific knowledge, but also in seeing that this knowledge finds its fruitful application. Under his influence the research associations have prospered, and at the same time D.S.I.R. has strengthened its connexions with industry by establishing a central Intelligence Division.

Sir Ben's influence has also been both valuable and extensive outside the domestic affairs of D.S.I.R. As an official member of the Defence Research Policy Committee (see p. 251 of this issue) he has shared the responsibility of defining the general scientific needs of the Armed Services, and, where necessary and possible, has seen that the facilities of D.S.I.R. have been available for work in this field. He has also been an official member of the Advisory Council on Scientific Policy, through which he has been directly concerned with a wide variety of topics that fall within the field of civilian science, and most particularly with the problem of scientific man-power. Since 1953 Sir Ben has, in addition, been president of the European Organization for Nuclear Research. Sir Ben's voice will be much missed in the Council rooms to whose work he has always contributed with wisdom, and with force tempered by good humour. Although he has now come to the end of his official term of service at D.S.I.R., it is to be hoped that the country will still be able to learn his opinions about the broader affairs of science, and that he will find the opportunity to make his views on science and industry, as well as on scientific education, known to increasingly wider audiences.

Prof. H. W. Melville, F.R.S.

Prof. H. W. Melville, Mason professor of chemistry in the University of Birmingham since 1948, succeeds Sir Ben Lockspeiser as secretary of D.S.I.R. Prof. Melville was educated at George Heriot's School, Edinburgh, and at the Universities of Edinburgh and Cambridge. During 1933–44 he was a Fellow of Trinity College, Cambridge, and between 1940 and 1948, before taking up his appointment in Birmingham, professor of chemistry in the University of Aberdeen. He was elected to the fellowship of the Royal Society in 1941, and was awarded the Davy Medal last year for his distinguished contributions to the chemistry of macro-molecular substances. His researches before 1939 were concerned with the mechanism of gas-phase reactions, especially in slow and explosive combustions, and with the photochemistry of polyatomic molecules and photosensitized reactions. Inquiries into gas-phase polymerization reactions, which Prof. Melville took up during this period, laid the foundation for much of his post-war researches. These were mainly directed to the study of liquid phase polymerization ; and the development and combination of a series of completely new physical methods, including highly sensitive methods of following liquid phase reactions, led to the complete eludication of the kinetics and chemistry of this process. Considerable advances were also made in the study of the breakdown of large molecules, while the use of radioactive tracers allowed Prof. Melville to extend his investigations on the chemical side. All these developments have shown how to synthesize completely new types of macro-molecules. Much of this will no doubt be reviewed by Prof. Melville in the Bakerian Lecture of the Royal Society which he is due to deliver in the near future.

Prof. Melville brings to his new responsibilities not only great achievements as an investigator, but also considerable experience of advisory work on behalf of the Government. He was a member of the Advisory Council of D.S.I.R. between 1946 and 1951, and has also served on the Advisory Council of the Ministry of Supply ; on the Research Council of the British Electricity Authority ; on the Fuel Research Board ; and on the Advisory Council of the Ministry of Fuel and Power. He was also a member of the Royal Commission on University Education in Dundee. Many new responsibilities will now fall to his lot, including not only the direction of D.S.I.R. but also the representation of its interests on the Advisory Council on Scientific Policy and on the Defence Research Policy Committee. Prof. Melville's great record of achievement and service provides every confidence that the further development of D.S.I.R. has been entrusted to a man who has all the imagination and drive necessary to fulfil his task.

Directorship of the National Physical Laboratory :

Prof. G. B. B. M. Sutherland, F.R.S.

Prof. G. B. B. M. Sutherland, professor of physics and director of the Biophysics Research Centre in the University of Michigan, has been appointed director of the National Physical Laboratory. It is expected that Prof. Sutherland will take up the appointment in September next ; Dr. R. L. Smith-Rose will continue as acting director until Prof. Sutherland takes up duty. Prof. Sutherland is a leading authority on infra-red spectrum analysis but of recent years has developed especial interests in the field of biophysics. He was educated at the Morgan Academy, Dundee, and the University of St. Andrews. From 1935 until 1949 he was a fellow of Pembroke College, Cambridge. During the early part of the Second World War, Prof. Sutherland was assistant to the Director of Scientific Research at the Ministry of Supply. In 1941 he was made head of a group carrying out research in Cambridge for that Ministry, the Ministry of Aircraft Production and the Admiralty on the structure of hydrocarbons. This work led to significant improvements in aviation fuels. In 1947 he became reader in spectroscopy at Cambridge and in 1949 was appointed to his present post in the University of Michigan. He was elected a Fellow of the Royal Society in 1949.

Zoology in University College, Swansea: Prof. E. W. Knight Jones

Dr. E. W. Knight Jones, deputy director of the Marine Biology Station at the University College of North Wales, Bangor, has been appointed to be the first occupant of the chair of zoology in the University College of Swansea. Educated at Epsom College and at the University College of North Wales, Dr. Knight Jones graduated with first-class honours in zoology in 1938 and started research on the nervous system of *Saccoglossus*, one of the Enteropneusta. He was awarded a Meyricke Scholarship of Jesus College, Oxford, in 1939 and continued his research under Dr. (now Prof.) J. Z. Young. At the outbreak of war he joined the Army, being commissioned in the Royal Artillery. He was promoted captain, mentioned in dispatches and wounded during the crossing of the Rhine in 1945. On demobilization he returned to Oxford to complete his studies on the enteropneustan nervous system, for which he was awarded the degree of D.Phil. From 1946 he was engaged on shellfish research under Dr. H. A. Cole in the Ministry of Agriculture and Fisheries, being naturalist-in-charge at the then newly formed Burnham-on-Crouch station, until he returned to Bangor in 1950 on the foundation of the Marine Biology Station. Much of Dr. Knight Jones's work has been concerned with problems of larval settlement, to which he has made contributions of fundamental importance. He has shown the importance of gregariousness during spat-fall and has directed attention to the constancy of direction of metachronal waves and its relation to the direction of beat in the ciliary tracts of both larvæ and adults. Recently he has shown that many planktonic animals are sensitive even to small changes of hydrostatic pressure, a finding that is likely to prove of great significance in relation to vertical movements.

Institution of Electrical Engineers: Awards

Sir Stanley Angwin has been elected to honorary membership of the Institution of Electrical Engineers in recognition of his outstanding life's work in the field of telecommunication, both national and international, and of his distinguished services to the Institution. Sir Stanley, who was engineer-in-chief of the Post Office during 1939–46, is a past president of the Institution and was awarded the Faraday Medal of the Institution in 1953 (see *Nature*, 171, 287; 1953).

Prof. G. W. O. Howe

The thirty-fourth award of the Faraday Medal of the Institution has been made to Prof. George William O. Howe for his pioneering work in the study and analysis of high-frequency oscillations and on the theory of radio propagation, and for his outstanding contributions to engineering education. After graduating from Armstrong College (now King's College), University of Durham, Prof. Howe gained industrial experience in electrical engineering, and then in 1905 went to the Imperial College of Science and Technology, London, as a lecturer, being appointed assistant professor of electrical engineering in 1909. For a brief spell in 1920 he was head of the Department of Electrical Standards and Measurements of the National Physical Laboratory, and in the following year he was appointed James Watt professor of electrical engineering in the University of Glasgow, a position he held until his retirement in 1946. During 1920–22 he was editor of the *Radio Review*, and in 1923 became editor of the *Wireless Engineer*, an office he still holds. Prof. Howe's association with the Institution of Electrical Engineers began in 1905 when he was elected an associate member. He took a prominent part in the formation of the Wireless (now Radio and Telecommunication) Section of the Institution in 1919, and in 1924 he gave the first of the Institution's Faraday Lectures, his subject being "World-Wide Radio Telegraphy".

New York Academy of Medicine: Awards

The Medal of the New York Academy of Medicine has been awarded to Dr. Eugene Floyd DuBois for his fundamental contributions to the science of metabolism and the understanding of disease, for his work in the development of clinical science and medical education and for his services to the United States during two World Wars in the solution of physiological problems in aviation medicine and submarine warfare. The Medal was founded twenty-seven years ago and is awarded from time to time for distinguished service in medicine, the present award being the tenth to be made. Dr. DuBois, who was formerly professor of physiology and biophysics in Cornell University Medical College, New York, is probably best known for his studies of the physical mechanism of fever, particularly his calorimetric work in skin temperature and heat radiation. The Academy has also presented a plaque to Dr. Malcolm Goodridge for his outstanding services to the Academy, particularly as president during the early years of the Second World War.

Imperial College of Science and Technology

Questions were raised in the House of Lords on January 25 regarding the expansion of the Imperial College of Science and Technology. The Secretary of State for Commonwealth Relations, replying for the Lord President of the Council, said that, in view of the urgent need to increase the output of scientists and technologists in Britain, the Government has decided to adhere to the scale of development for the Imperial College originally announced. To enable this decision to be given effect, new premises for the Imperial Institute will be provided elsewhere. He said that he does not think there is now anything to hold up the original building plan of the Imperial College; the Government is fully aware of the urgency of the problem of expanding technological education.

Manchester College of Science and Technology

Speaking at the associateship ceremony of the Manchester College of Technology on November 26, the principal, Dr. B. V. Bowden, referred to the conferment of a Royal Charter on the College, with the title of the Manchester College of Science and Technology, and paid tribute to the efforts of the past: beginning in 1824 with the building of a Mechanics Institute, which was opened in May 1827, successive developments led to a much larger Institute in 1857, to a Technical School in 1883 and then to what Mr. A. J. Balfour described, in opening it in October 1902, as "the greatest fruit of this kind of municipal enterprise in the country". Three years later, the relation with the University of Manchester was established, under which the University's Faculty of Technology has ever since been in the College of Technology and the professorial staff of the College have been members of the University Senate. Even half a century ago the building just then completed was too small to meet the demands being made upon it, and the building expected to be completed shortly is a little bigger than the one for which plans were first approved in 1914. Two years before the latter date, however, the principal, Dr. Maxwell Garnett, had pleaded for more advanced education for engineers, claiming that while the practical man was as necessary as ever, the practical man of the day was the man who could readily apply theory to practice, when practice was governed by something better than rule of thumb. At that time, the position of Britain in the vanguard of progress was already threatened by developments attributable to the growth of the technical institutions in Germany, the Netherlands and Switzerland, where by 1910 there were twelve such institutions of university rank as against two in Britain. Dr. Bowden said that nowadays the survival of Britain as a great nation depends on the production of many more scientists and technologists than are at present being trained; after referring to the value of the part-time training given by the College, he added that it is hoped to develop an institution which would derive its strength from the traditions of the past hundred and thirty years, but which would be specially adapted to meet the changing needs of to-day, contributing both the ideas and the men which industry needs.

School for Advanced Study at the Massachusetts Institute of Technology

A School for Advanced Study has been established at the Massachusetts Institute of Technology, with Dr. Martin J. Buerger, professor of mineralogy and crystallography, as director. The School will be similar in its objectives to the Institute for Advanced Studies at Princeton, but will differ in that it will be an integral part of the Institute and serve as an extension of the level pursued at the existing Undergraduate and Graduate Schools. These three Schools will thus constitute the three 'horizontal' levels of the Institute, and the staff will continue as members of the five 'vertical' organizations, namely, the Faculties of Science, Engineering, Architecture and Planning, Industrial Management, and Humanities and Social Studies. For the moment, the staff of the School for Advanced Study consists solely of the director and a secretary. Scholars will be invited by the Institute to pursue advanced study and will have the status of Fellows in the School. Up to now there have been approximately a hundred such people a year, from fifteen countries, studying at the Institute, and they have been registered as 'guests' or 'visiting Fellows'. It is hoped that ultimately the new School will provide a centre and adequate housing for Fellows and guests and, by means of special programmes and other schemes, arrange for them to meet in informal conferences among themselves and with the permanent staff of the various Faculties of the Institute. Dr. Buerger, who will assume the office of director on July 1, was a student at the Institute in 1920 and has been on the staff since 1925, becoming a full professor in the Department of Geology in 1944. A former president of the Mineralogical Society of America, he is widely known for his studies in theoretical mineralogy and for the development of new theories of crystal structure analysis.

Nuclear Weapons and Civil Defence

The first of a series of pamphlets in Vol. 1 of the "Manual of Civil Defence", prepared by the Home Office and Scottish Home Department, is one on "Nuclear Weapons" (pp. 55. London: H.M.S.O., 1956; 2*s*. 6*d*. net), and replaces "Atomic Warfare" ("Basic Training", Vol 2, Pamphlet No. 6). Freely illustrated with photographs, diagrams and maps, and lucidly written so that the intelligent layman should have no difficulty in understanding the exact nature of the hazards of nuclear explosions and what can be done to mitigate them, it is nevertheless not a popular exposition for the general public, and something much simpler and more concise would better serve to bring home to the ordinary citizen the value of those few simple precautions which they could themselves take to reduce casualties outside the immediate area of an explosion. The major part of the pamphlet is concerned with the hazards from nuclear radiation, including the immediate and delayed dangers and protection from fall-out as well as the control of exposure to radiation in contaminated areas, but there are chapters on the fire risk and on blast. It is, in fact, in these chapters that the pamphlet best indicates the contribution which common-sense and such simple measures as white-washing windows and remaining under cover can offer against thermal radiation and blast, respectively, and the pamphlet could assist in providing the basic information and stimulating simple practical measures needed. That such measures are severely limited in scope, and that the tactical and administrative measures which are not considered in the pamphlet are of the utmost importance, will not be gainsaid. Nevertheless, a campaign of public education is of the utmost urgency to enable ordinary people to take whatever precautions are in their power, some of which, such as the construction of trenches or shelters and the choice of one type of house as against another, demand a certain amount of foresight and preparation.

Preservation of the Lake District

The report and newsletter for 1955 of the Friends of the Lake District (pp. 25. Ulverston: Friends of the Lake District, 1955) comments on the growing support for the idea that national parks should be financed nationally, and the proposal that some part of the annual interest on the National Land Fund should be used for this purpose has been widely canvassed. A detailed resolution has been submitted to the Chancellor of the Exchequer by the British Travel and Holiday Association, and the Financial Secretary to the Treasury has received a deputation of members of Parliament on the matter and has agreed to raise with the Chancellor the possibility of including some suitable provision in the Finance Act accompanying the next Budget. Moreover, the Minister of Housing and Local Government, at a recent conference of park planning authorities, in suggesting that the time had come to review the working of the Act, emphasized his full support for any efforts to resist undesirable encroachment or disfigurement in the national parks. The newsletter recapitulates in some detail the events which led, in June 1955, to the decision of the North-Western Electricity Board to lay underground the whole of the much-debated line up Borrowdale, between Keswick and Resthwaite, including a loop-line along the far side of Derwentwater, without extra charge to individual consumers in the valley. This result is attributed to the intervention of the Minister of Fuel and Power, following the representations made by the National Parks Commission to that Minister and to the Minister of Housing and Local Government. Negotiations in regard to Langdale and in regard to Patterdale continue. The society, with the Council for the Preservation of Rural England, has also reached a satisfactory agreement with the Forestry Commission in regard to any land within the 300 square miles of the central Lake District which the Commission might acquire and which was not under woodland in 1936. The National Trust has also agreed in replanting its woodlands at Loweswater and above Buttermere to bring in a firm policy of introducing or carefully re-generating hardwoods wherever the ground is not too wet.

Brazilian Association for the Progress of Science

THIS year's meeting of the Brazilian Association for the Progress of Science will be held at Ouro Preto (Minas Gerais) during July 2–7, and as planned at present there will be eighteen sections, although this number is likely to be reduced later. The main themes for the meeting will include "Problems of the Atomic Age" (Physics Section), "The Problem of Petroleum in Brazil" (Geology Section) and "University Teaching of Science" (Education Section). Other topics of special interest are "The Use of Isotopes in Technology", "Ionospheric Exploration", "Metallurgy of Radio-active Metals", "Animal Movement" and, possibly, "*Rauwolfia serpentina*". The great natural resources of Minas Gerais State and the existence of a mining school in Ouro Preto give a specially geological regional interest to the meeting, which will be brought out in various papers to be read on mining for iron and gold, on petroleum and on mineralogy and geology generally. Among the British contributions to the meeting will be a showing arranged by the British Council of a number of recent scientific films, and an address on "The Teaching of Science and Technology in British Universities" by Mr. F. M. Beatty, the British Council's science officer in Brazil.

Oil and Colour Chemists' Association: Eighth Technical Exhibition

THE eighth technical exhibition of the Oil and Colour Chemists' Association, organized by the London Section of the Association, will be held during March 20–22 in the Royal Horticultural Society's New Hall, Grey Coat and Elverton Streets, London, S.W.1, at the following times: March 20, 3 p.m.–8.30 p.m.; and March 21 and 22, 11 a.m.–7.30 p.m. As before, the theme of the exhibition will be the presentation of technical advances in those industries supplying the paint, varnish, printing ink, linoleum and other allied industries. The area covered by the exhibition and the total number of companies and research associations exhibiting (eighty-two in all) are the largest yet reached. A ninety-two page catalogue of the exhibition has been prepared and is available. Admission to the exhibition is free. Further information can be obtained from the general secretary, R. H. Hamblin, Oil and Colour Chemists' Association, Memorial Hall, Farringdon Street, London, E.C.4.

Optics Meetings in the United States

THE International Commission for Optics will meet this year in the Massachusetts Institute of Technology, Cambridge, Mass., during March 28–April 3, and will devote four days to a symposium on "Frontiers in Physical Optics", which will be open to all interested. At the symposium the following topics will be discussed: new phase-contrast and interference microscopic and measuring devices; thin films and filters; meteorological optics; and nuclear optics. The main papers for these sessions have already been invited and prepared, but time will be reserved for free discussion. In addition to these events, the regular spring meeting of the Optical Society of America will be held during April 5–7 in Philadelphia, Pennsylvania, and this also will be open to all interested. Further information about the meetings can be obtained from Dr. S. S. Ballard, Visibility Laboratory, Scripps Institution of Oceanography, University of California, San Diego 52, Calif.

Announcements

RAYMUND L. ZWEMER, formerly chief of the Science Division of the Library of Congress, has been appointed head of the Division of International Co-operation for Scientific Research in the Natural Science Department of the United Nations Educational, Scientific and Cultural Organization. He will be responsible for Unesco's relations with international scientific unions and other organizations concerned with scientific research on an international scale.

SIR ERIC RIDEAL is to deliver a course of three lectures on "Colloids and their Behaviour" at the Royal Institution on February 28, March 6 and 13 at 6 p.m. This is a refresher course intended primarily for school teachers. Members of the London Branches of the Science Masters' Association and the Association of Women Science Teachers will be notified by their Associations about applications for tickets; non-members should apply to a local branch secretary of one of the Associations.

THE Institution of Naval Architects is offering two scholarships in naval architecture—the I.N.A.–Elgar-Martell of £275 a year, and the Vickers-Armstrongs of £220 a year—both of which are tenable for three or four years at a university institution. They are open to British subjects, less than twenty-three years old, who have been employed in shipbuilding. Applications should be made by May 31 to the Secretary of the Institution at 10 Upper Belgrave Street, London, S.W.1.

THE Council of Europe and the High Authority of the European Coal and Steel Community will award jointly a number of fellowships this year for research into problems of European interest. The fellowships will be worth 300,000 francs each (about £300). The fields of work applicable are as follows: efforts to achieve European integration by co-ordination in the political, social, economic, scientific or educational fields; European civilization in relation to contemporary problems (philosophy, history, literature or the arts); economic, legal or social problems relating to the European Coal and Steel Community and its institutions. Candidates from Great Britain should obtain their application forms from the Education Division, British Council, 65 Davies Street, London, W.1, and return them before March 15.

THE NATURE CONSERVANCY

ANNUAL REPORT

THE Nature Conservancy has virtually completed the building up of its organization and the initial surveys of areas of scientific interest, and in the year ended September 30, 1955, covered by its sixth annual report*, it has been concerned mainly to secure the most effective use of the resources now at its disposal. During the year, the Conservancy declared sixteen new nature reserves in Britain and added to four previously declared, bringing the total acreage to 79,035 acres in thirty-five reserves. The whole programme for national nature reserves was reviewed during the year and, except for a handful of sites presenting special difficulties, it is hoped to complete the programme of declarations within the next four years. Unfortunately, some of the areas of special scientific interest which cannot be included in this programme are suffering considerable damage and losses, and the Conservancy hopes that more local authorities will use their powers to create local nature reserves under the National Parks and Access to the Countryside Act, and also that more voluntary action will be taken by both national and county trusts and societies. Of the three such local reserves noted in this report, that at Ravenglass had another successful season, at Aberlady Bay the legal validity of by-laws applicable to the foreshore made by the Nature Conservancy and appropriate local authorities was established, and by-laws for the protection of the scientific interest in the Castle Eden Denes Local Nature Reserve have been submitted to the Secretary of State for approval.

Financial stringency, as anticipated, greatly embarrassed the Conservancy, compelling postponement of fencing of reserves and long overdue woodland operations. The grant-in-aid received during the year for the general expenses account was £154,500, and expenditure was £157,992, while the grant-in-aid on capital expenditure account was £47,500, including £30,000 for purchase and equipment of the new London headquarters at Belgrave Square, and expenditure was £47,256. Fourteen new research grants, totalling £10,934, were awarded, and twenty-seven grants were continued or renewed; but the funds available for this purpose and the programme of scientific work were quite inadequate. The implications of this financial position and the comments of the Conservancy on co-operation and co-ordination and the like are discussed elsewhere in this issue (p. 245); references to the new nature reserves have already been made in these columns. The following notes are accordingly limited to the scientific work of the Conservancy, whose total staff is now 130, forty-two of whom are scientifically qualified.

The two research stations at Merlewood, More cambe Bay, and at Furzebrook, Poole Harbour, and the Field Station at Anancaun, Kinlochewe, have now completed two seasons of field-work, and the Moor House Field Station on the Westmorland Pennines three. Much of the summer of 1955 was particularly favourable for field-work. The primary work of survey continued, particularly for existing and projected nature reserves; but the emphasis is shifting to intensive specialist investigations of sites of major importance, particularly in connexion with programmes of research. A more intensive survey of distributions is also being carried out with the assistance of such bodies as the Botanical Society of the British Isles. In this work amateur botanists are providing many of the observations. Other examples are the duck counts and the comprehensive survey of inland waters being undertaken by the Wildfowl Trust. Two tentative forest maps have been prepared for Scotland, the first showing the present distribution of native birch, oak, pine, alder and ash wood, and the second attempting to reconstruct the distribution of Scottish forests in the first four centuries of the Christian era, or as it could have been to-day in the absence of man's activities.

Such surveys can be of great value in decisions on land use, and during the year at the Forestry Commission's Gisburn Forest, hardwoods and coniferous trees have been planted on a series of plots statistically designed to yield precise comparisons of productivity and changes in soil status for the different types of timber, and also for sheep-rearing. By this means it is hoped to secure fundamental data of effects of grazing and tree-growth together with practical data on the economic use of hill lands of a type very common in northern and western Britain. Nature Conservancy scientists have collaborated with the Natural Resources (Technical) Committee in a review of the relative advantages and disadvantages of forestry and agriculture on marginal land. An extensive survey of floods and soil erosion resulting from modern changes in land use was begun in Scotland.

The ecological management programme for the Yarner Wood Nature Reserve on the edge of Dartmoor was initiated, with the principal long-term aim of re-constituting a naturally regenerating wood of the type believed once to have covered much of south-western England, and a favourable start was made in the experiments on reconstitution of high-altitude woodlands at Moor House. Investigations of soil invertebrates at Merlewood Research Station indicate that certain amino-acids essential for the maintenance of animal life are more abundant in the fallen leaves of some plants than of others, and free-living nematode worms are also being investigated with the view of determining what are the nematode faunas of soils and litters beneath natural and planted woodlands of different species of trees. A survey of wood ants showed that *F. rufa* is more abundant in the limestone woodlands near Grange-over-Sands but has declined over the past half-century in the Windermere area, apparently as a result of invasion by bracken. On the Hartland Moor Nature Reserve, the distribution of all ant species has been mapped by transect over 10 hectares, and a more detailed permanent quadrat has been established over about 600 square metres.

Intensive studies of peat nutrients have been started at Merlewood Research Station, and work on moorland animals at Moor House has revealed interesting relationships between the moth *Coleophora caespititiella* and its food plant *Juncus squarrosus*

(heath rush). With the co-operation of the Ministry of Transport and Civil Aviation radar station at Great Dun Fell (2,780 ft.) of the Meteorological Office, it is hoped to initiate a range of automatic recordings of meteorological data at that point, which will in future be compared with those being taken at Moor House and at Alston. Establishment of the Cairngorms Nature Reserve has made possible a partial filling of a serious gap in the snow survey of Britain, and autographic temperature-recording has now started at Loch Etchachan (3,058 ft.), where weekly readings are taken during April–October.

The present status in Britain of the hare has also been investigated, as well as the population density and feeding habits of the buzzard in sample areas throughout the country. No evidence of an extensive switch of diet by predators in directions harmful to human interests has so far been traced to the disappearance of rabbits. The measurement of long-term changes in the vegetation on grasslands, particularly where rabbit-grazing has been suddenly reduced by myxomatosis, continued, and at Bridgwater Bay measurements were made of the rate of shingle movement along the beach and its relation to the growth of the cord grass, *Spartina townsendii*. At Braunton Burrows the closing of blow-outs by brushwood and hessian fencing, together with the planting of *Ammophila arenaria*, increased the height of the coastal dune ridge by five to six feet, while the untreated central ridge was lowered by a similar amount and the inner ridge encroached landward by about 25 ft. a year. As a result of the Conservancy's continued experiments on spraying of roadside verges and hedgerows, the Ministry of Transport and Civil Aviation issued a circular on the use of selective weedkillers containing substituted phenoxyacetic acids for control of roadside vegetation to all appropriate local authorities. The Nature Conservancy also investigated during April–June 1955 complaints of killing of lambs by golden eagles in Lewis, as a result of which no amendment of the law forbidding the killing of this bird was considered necessary.

A list of scientific publications of the Conservancy is included in the report.

THE NATIONAL PARKS COMMISSION, GREAT BRITAIN

ANNUAL REPORT

WITHIN the limits set by its financial resources and the neglect to implement fully the administrative provisions of the National Parks and Access to the Countryside Act, the sixth annual report of the National Parks Commission, covering the year ended September 30, 1955*, gives a reasonably encouraging record of progress. The education of the public and of government departments, public corporations and local authorities has been patiently, tactfully and persistently pursued. Firm opposition has been maintained, so far as the Commission's powers permit, to proposals which threaten the purposes for which the parks were created, and although there is no immediate prospect of extending the list of areas designated as national parks the Commission is giving increasing attention to the designation of areas of outstanding natural beauty. Administrative arrangements for the Exmoor and Yorkshire Dales National Parks have not yet been settled, nor for the Brecon Beacons Park or the Northumberland National Park designated on September 20, 1955. At the same time, the Border National Forest Park, including Kielder Forest and the adjoining forests of Kershope in Cumberland and Newcastleton and Wauchope in Roxburghshire, was established in a joint notice issued by the Forestry Commission and the National Parks Commission.

Generally, the administration of the parks proceeded smoothly, and the Commission advocates the introduction of a system of retirement by rotation for each park planning authority, so as to secure some flexibility and continuity of membership. The Commission commends particularly the activity of the Peak Park Planning Board in securing public access to the Kinder and Bleaklow plateaux: the seven access agreements already approved by the Minister cover some 9,345 acres. Much positive action has been taken in providing car parks, the improvement of caravan sites and the removal of undesirable advertisements; and the Board's warden service has earned the gratitude of landowners and farmers for their work, especially for their help in freeing sheep during winter snowstorms. The Lake District Planning Board has likewise given much attention to camping and caravan sites, car parks, the planting of trees and removal of offensive advertisements, and its lease of a large house at Hassness, Buttermere, to the Ramblers' Association Services, Ltd., for use as a hotel is characterized as a milestone in the history of national parks in Britain. At the opening ceremony the Commission's chairman, Lord Strang, congratulated the Board also on being the first park planning authority to provide a new public right-of-way, and on opening the first camping and caravanning site to be available under the powers of the Act. The activities of the other park planning authorities have been on similar lines. The Snowdonia Joint Advisory Committee, for example, is giving increasing attention to publicity, and, like the Pembrokeshire National Park Committee, to the clearance of disfiguring structures from sites used during the War by the Services. The Dartmoor National Park Committee has been asked to deal informally with the denial of access, and the Committee has diligently pursued various methods of dealing with the litter problem. The programme of the North York Moors Park Planning Committee includes a scheme for the protection of the wild daffodils in the valley of the proposed Farndale Local Nature Reserve and publication of a guide book to the Reserve.

In referring to the question of a National Park in Cornwall which has recently been examined once more, the Commission expresses some doubt whether the long, narrow and discontinuous coastal stretches of Cornwall are in all respects suitable for designation as a national park, and whether their administration as such would be practicable. It proposes, therefore, to consider designating coastal areas in Cornwall, and also in Devon and Dorset, with as much of their hinterland as merits inclusion, as areas of outstanding beauty. The experience gained in this way should show whether the provisions of the Act in regard to such areas are adequate, or whether some further legislative measure of protection is required. The Commission has in the meantime already made proposals for designating the Gower Peninsula and the

* National Parks and Access to the Countryside Act, 1949. Sixth Report of the National Parks Commission for the year ending 30th September, 1955. Pp. iv+60+8 plates. (London: H.M. Stationery Office, 1955.) 4*s*. net.

Quantocks as areas of outstanding natural beauty, and is in informal consultation with the county councils about the Surrey hills and the Lleyn. The effect of such designation is chiefly to apply to such areas the powers conferred by the Act for the preservation and enhancement of natural beauty, and projects for these purposes, approved by the Minister, qualify for Exchequer grants of 75 per cent.

The other area considered by the Commission during the year as a possible national park, the Broads, presents problems not encountered elsewhere. The Broads themselves are diminishing in area, and this encroachment of land on water results from a complicated natural process not yet fully understood. Neither the origin of the lagoons nor the causes of their in-filling has yet received more than superficial investigation, and the Commission considers that such a scientific survey is an essential preliminary to any decision as to whether and at what points and at what cost restoration could be undertaken with any hope of success. Arrangements for such a survey are being discussed with the Nature Conservancy and the Ministry of Housing and Local Government, and it is hoped that the task will be undertaken by the Nature Conservancy in the near future.

Disappointment is again expressed at the slow rate of progress with the 'long distance routes', and the Commission's dissatisfaction with the Minister's decision to uphold the Manchester Corporation's contention in regard to the Pennine Way and Crowden Great Brook is recorded. Little progress was made in the establishment of new rights of way for the Cornwall north and south coast sections of the South-West Peninsula coast path; but more encouraging reports are given of the Pembrokeshire coast path, the Flamborough coast route and the South Downs route; a Welsh Highland route is under consideration. The Commission has been able to increase its publicity activities and plans to make more information available about the national parks and the long-distance routes and, as already noted, the ever-present problem of litter receives increasing attention under the publicity campaign with the Country Code.

In regard to development questions, the Commission notes that the Service departments consult the Commission on their proposals for the acquisition of land and erection of buildings and associated works required for the defence programme when these fall within areas in which the planning authorities know the Commission is interested. To ensure that the Commission is made aware of such proposals at the earliest opportunity and to facilitate liaison, the Commission now proposes to supply the Service departments with copies of special maps showing the areas in which it is interested. The Commission's views on the reconciliation of the claims of amenity with the duties of area boards to supply electricity at the lowest possible cost are reiterated; as a result of a general discussion with the Central Electricity Authority in which the Commission stressed the value of early consultation on new projects in areas of special landscape value, it is hoped to build up local liaison and by its means reach acceptable compromises. Meanwhile, the Ministry of Fuel and Power announced on June 27 that the North-Western Electricity Board has agreed to lay underground the whole of the new supply lines as far as Rosthwaite, including the circuit of Derwentwater, but decision on the remaining sections of the Borrowdale line are awaited. The Board has also announced that there will be no additional charge to consumers for the Hartsop scheme or in any other area where the Board is placing lines underground to preserve the beauty of the existing scene. As regards the North Wales hydroelectric power proposals, the Commission, while not offering outright opposition to the Bill embodying the Ffestiniog and Rheidol schemes, has submitted a detailed memorandum directing attention to points requiring special consideration, and it insists that it is essential that its representations should reach the Parliamentary Committee in the form in which they are made. This procedure has now been agreed with the Minister.

In regard to the proposed road racing circuit in the Peak District National Park under discussion by the Derbyshire County Council, the Commission records the opinion that it cannot see how any such proposals could be consistent with the maintenance of the area as a national park. The Conference of Park Planning Authorities held in London on July 26 provided a valuable opportunity for discussion of problems and for the demonstration of community of view.

THE DEVELOPMENT OF THE POLAROGRAPH

THE thirtieth anniversary of the invention of the polarograph was marked by Prof. J. Heyrovský's recent visit to Great Britain at the invitation of the Polarographic Society, when he took the opportunity of delivering his presidential address to the Society, given in London at the Royal Institution on November 16. Prof. Heyrovský began by pointing out that 1925 was to some extent a nominal date for the invention of the polarograph. Like most inventions, it took a year or so to conceive and develop. The original design is still in use, and its performance is, in fact, superior to many of the commercial instruments which have been developed from it.

The exact reproducibility of the current-voltage curves obtained with the dropping-mercury electrode had made it worth-while to construct an automatic device (the polarograph) for the purpose of recording such curves. Therefore, in the original meaning of the word 'polarography' the use of an exactly reproducible electrode was of greater significance than the use of automatic recording. In recent years, however, there has been a tendency to neglect the importance of reproducibility and to apply the term 'polarography' to the automatic recording of current-voltage curves in general. Nevertheless, Prof. Heyrovský considered it desirable to restrict the use of the word to the investigation of all aspects of the dropping- or streaming-mercury electrode. These include a number of phenomena that are studied by current-time or potential-time curves. The current-voltage curves of solid electrodes, which were studied many years before the introduction of the polarograph, were not reproducible and so did not constitute polarography in the strict sense of the word, even though they might be obtained by means of the polarograph. Such considerations govern the inclusion of material in the well-known bibliography which is maintained by the Polarographic Institute of the Czechoslovak Academy of Science.

With regard to the capillary, the mercury flow-rate should not exceed 2 mgm./sec. In concentrated solutions, failure to adhere to this condition leads to unwanted maxima of the second kind, and Kryukova has attributed these to stirring of the solution in the vicinity of the drop. Kinks in the plastic tube which joins the capillary to the reservoir can be discouraged by a specially bent capillary assembly. The introduction of the horizontal capillary by Smoleř is of considerable interest, for the resultant current-voltage curves are smoother than those obtained with the vertical capillary, disturbances are absent and the oscillations due to drop formation are greatly reduced. Current-time curves of single drops show that the horizontal electrode obeys the Ilkovič equation more exactly than the vertical one. The horizontal electrode is conveniently achieved by bending the tip of a vertical capillary, so that the last 2 mm. or so is in the horizontal plane. The control of drop-time by the use of a small electromagnetic hammer is now proving useful, not only for the synchronization of the twin-electrode systems employed in subtractive or derivative polarography, but also for any circumstances in which it is desirable to reduce the drop weight from its natural value. The streaming-mercury electrode, originally introduced for oscillographic experiments, has proved useful in ordinary polarography, and an equation for its diffusion current has been introduced by Ríus, Llopis, Polo and Koryta.

Small fluctuations in the potentials of the two mercury pools as well as in the rate of flow of mercury through the twin capillaries have proved a practical hindrance to the elegant subtractive method. On the other hand, derivative curves are readily obtained by means of two synchronized electrodes immersed in one solution and differing in potential by about 10 mV. throughout the polarogram. Vogel and Říha have obtained derivative curves from a single capillary by means of a condenser-resistance circuit (their publication appeared about a year before that of Lévêque and Roth), and in this case it is necessary for the applied voltage to vary linearly with time. In yet a third method, a single capillary can be made to yield derivative curves by the use of a mirror galvanometer having a special 'two-coil' suspension. Here, the passage of electrolytic current through the first coil induces its time-derivative in the second one. The general advantage of the derivative curve is that its maximum gives information both on the half-wave potential (the quality) and on $\mathrm{d}i/\mathrm{d}E$ (the quantity) of the electroactive substance. On the other hand, the sensitivity is only about 5 per cent of that obtainable from the normal polarogram. Furthermore, apart from the method, which employs twin capillaries, the half-wave potential depends on both the rate and direction of the applied voltage. Any discussion of derivative polarography would be incomplete without reference to the square-wave polarograph developed at Harwell by Barker and Jenkins; in its sensitivity, this instrument greatly exceeds any polarograph which has so far been developed.

Attention was directed by Prof. Heyrovský to the little-known Kaloušek method for studying the reversibility of electrode processes. By means of a commutator, the electrode is subjected to alternate cathodic and anodic polarization at between 5 and 10 cycles/sec. In these circumstances, a metal such as zinc undergoes cyclic deposition and dissolution. In acid solution, the resultant single anodic–cathodic wave shows the reduction process to be reversible. On the other hand, the formation of a double wave in alkaline zinc solutions indicates an irreversible process.

During recent years, polarography has been successfully combined with the chromatographic technique of separation, a method known as 'chromatopolarography' having been devised by Kemula. Industrially, the polarograph is finding an ever-increasing application as a continuous service indicator. For such purposes, the mercury-pool anode is unsatisfactory, since the whole of the mercury is eventually converted to calomel. To meet this difficulty, the dropping-mercury electrode in halide solution has recently been introduced as a stable reference anode. The continuous determination of oxygen constitutes one of the more prominent examples of the continuous service application, and in this particular example the mercury-pool cathode has proved to be about a hundred times more sensitive than the dropping-mercury cathode.

An interesting biochemical application of polarography is to be seen in the apparatus of Šerák. Here, the oxygen uptake of tissue preparations can be accurately followed over a period of time. In the medical field, the polarographic diagnosis of cancer is based on Brdička's protein test, now almost twenty years old, in which, after precipitating the bulk of the proteins from the patient's serum, the filtrate is examined polarographically in the presence of hexamminocobaltic chloride in ammoniacal solution. When the patient is suffering from cancer or some feverish condition, an exceptionally large protein wave, due to muco-proteins, is observed. Prolonged experience of this test suggested that it is 80 per cent certain, but the modified test recently introduced by Balle-Helaers appears to be 100 per cent certain; this modification involves graded alkaline denaturation, before precipitating the proteins with sulphosalicylic acid.

In theoretical polarography, a new field has been opened up by Wiesner and Brdička's discovery of the kinetic current, which depends upon the rate at which depolarizer is being formed at the electrode surface. Kinetic currents are independent of reservoir height and possess temperature coefficients of the order of 30 per cent per deg. C. Such investigations have led to important information about rate-constants; for example, all four rate-constants of the mutarotation of α- and β-glucoses are derived in this manner. Brdička's study of the reduction waves of weak acids has also led to the consideration of the absolute rate of recombination of ions.

The cathode-ray oscillograph is finding increased uses in polarography. In this way, it is possible to follow the polarographic current-voltage curves on one mercury drop of 5–8 sec. duration. In an alternative approach, the potential-time curves are obtained.

THE GEOGRAPHICAL ASSOCIATION

ANNUAL CONFERENCE

THE annual conference of the Geographical Association, held at the London School of Economics and Political Science during January 3–6, was noteworthy this year for two main aspects, namely, the emphasis given to papers on London and the London Basin and the unusually large number of members who were present. All the lectures were very well attended and in several cases the seating accommodation in the lecture-theatre was over-full. The annual dinner, with the president, Mr. L. S. Suggate, in the chair, attracted more members than ever before, and the excursions on the last day of the conference, though more numerous than previous years, were considerably over-subscribed.

Mr. W. F. Grimes, director of the London Museum, opened the conference with an excellent summary of the present knowledge of London's prehistory. The London theme was taken up later by a series of papers ranging from Mr. A. F. Green's fascinating analysis of the problems of London's underground drainage to Prof. S. W. Wooldridge's interesting commentary on the relationship of London's railways to the relief and structure. Dr. J. H. Bird presented a critical résumé on the activities of the London docks, and Dr. M. J. Wise analysed the role of London in the industrial geography of Britain with particular reference to the recommendations of the Barlow Commission. Both these papers were followed by excursions, one to the docks and the other to industrial areas of East London. The past and present agricultural development of the London Basin was the subject of Dr. H. C. K. Henderson's paper, which was followed by a traverse by motor coach across the northern part of the London Basin to Luton. Another excursion crossed the southern part of the basin and in the afternoon visited the National Institute of Oceanography at Wormley, near Godalming.

Teaching matters were fully discussed by Mr. Suggate in his presidential address on "Some Aspects of Teaching Geography in the Grammar School". His paper was most enthusiastically received by a very large audience, conscious of the very great contribution that Mr. Suggate has made to the development of geography in school. Another very large audience heard a stimulating and provocative paper on river development by Dr. G. H. Dury, who commented, as an examiner, on mistakes commonly found in school examination scripts. Later he took a large party of members to examine a series of river meanders in Enfield. "Sample Studies" was the title given to a meeting sponsored by the Secondary Schools Committee of the Association. The subject was introduced by Mr. R. C. Honeybone, who stressed the value of the approach as one of many ways of teaching geography in a geographical manner and outlined its pitfalls. Mr. D. J. Cadman followed this introduction by a lesson to third-form boys on the Vauxhall Works at Luton as a sample of the British automobile industry.

Prof. A. E. Smailes presented an account of the Association's summer school held last August in Aix-en-Provence; Prof. P. W. Bryan showed two films on Snowdonia and Anglesey; and Prof. A. L. Banks read a paper on what is to most geographers an unusual topic, "Some Aspects of Medical Geography". This last was a combined meeting with the Institute of British Geographers and the Royal Geographical Society, and was held at the Society's house in Kensington.

In addition to the usual large and representative publishers' exhibition, the Association's Standing Committee for Visual Aids in collaboration with the National Committee for Visual Aids in Education and the Educational Foundation for Visual Aids mounted an exhibition of sample study material, projectors and recently published film-strips.

R. C. HONEYBONE

THEORETICAL PHYSICS

SYMPOSIUM AT ST. ANDREWS

THE presence of Prof. W. Heisenberg (Göttingen) as Gifford Lecturer in the University of St. Andrews was used to organize a short, rather informal, conference on theoretical physics during November 18–20. Unfortunately, Prof. Heisenberg had to return to Germany sooner than had been expected and so, regrettably, was unable to be present, but about fifty physicists, mainly from British universities and government establishments, attended. Four sessions were held, one of which was devoted to an informal discussion on the teaching of theoretical physics.

Dr. J. Hamilton (Cambridge) introduced the first session on field theory. In view of the recent confirmation of the existence of the antiproton, his talk was devoted to an account of calculations performed in Cambridge, in conjunction with Bethe, on the possible modes of annihilation to be expected for this particle. He showed that the application of general principles of conservation of angular momentum, isobaric spin and parity is sufficient to make predictions concerning this process in the presence of very light nuclei. In general, the annihilation is expected to occur with the production of π-mesons, the ratio of π^- to π^+ to be expected depending simply on the quantum numbers of the nucleon involved.

Dr. T. H. R. Skyrme (Harwell) gave an account of a relativistic variational method for calculating the properties of a real nucleon in *PS—PS* theory, and Dr. J. S. R. Chisholm (Cardiff) reported work on the *S*-matrix in neutral pseudoscalar derivative coupling theory. Dr. J. W. Leech (Queen Mary College, London) described a method for the calculation of long-range interatomic forces; an earlier treatment of this problem by Casimir and Polder led to an inverse seventh power potential, but he finds the dependence to be an inverse third power. Dr. W. K. Burton (Glasgow) described work done in conjunction with de Borde on the method of functional integration for Fermi systems. Dr. D. L. Pursey (Edinburgh) discussed the possibility of having an acceptable theory which, although not covariant in every respect, leads only to covariant observable predictions. Finally, the session on field theory was concluded by Dr. C. G. Kuper (Liverpool), who discussed roton excitation in liquid helium.

Prof. H. A. Bethe (Cambridge and Cornell) introduced the session on nuclear physics by an appreciation of the nuclear model of Brueckner and collaborators. This model uses a generalized Hartree–Fock method and attempts, with considerable success, to deduce a self-consistent nuclear potential from the force between two free nucleons. A principal aim of the theory is to show that, using only such two-body forces, one can achieve nuclear saturation. Prof. Bethe gave an account of his own independent calculations on nuclear energy and radius, in which he has succeeded in taking complete account of the Pauli principle, and he also reported success, with Goldstone (Cambridge), in dealing with the repulsive core of the two-body nuclear potential. Preliminary numerical calculations (not taking account of the repulsive core), using a minimization procedure for the energy, show fair agreement for nuclear binding energy, but a nuclear radius one-third that of the actual radius. Proper treatment of the repulsive core, now in progress, will certainly change both results in the right sense.

There followed four short papers, in the first of which Dr. H. Primakoff (Oxford) discussed the nuclear absorption of μ-mesons. Then Dr. R. Nataf (Edinburgh) spoke on the foundations of the Bohr–Mottelson nuclear model, and Dr. S. Dedijer (Edinburgh) analysed, in terms of the independent particle model, the similarity in the variation of binding energy of the last neutron for nuclei near carbon-12 and oxygen-16. In the last contribution to this session Prof. N. Kemmer (Edinburgh) proposed a classification of many-body forces in the lightest nuclei based on representations of the symmetric group.

The session on solid state theory was opened by Prof. M. H. L. Pryce (Bristol), who described the information obtained from studying the fine structure of the paramagnetic resonance absorption of ions such as cupric in crystals. He went on to describe the distortion of the hydration sphere of the ion which, by the Jahn–Teller effect, arises from the degeneracy of the electron wave function in a fully symmetrical environment. This degeneracy may or may not be fully removed by the distortion. If rotation about an axis remains free, the system becomes equivalent to a particle moving in an annular potential well. Prof. Pryce finally suggested an analogy between this situation and the Bohr–Mottelson model of the atomic nucleus.

Dr. E. H. Sondheimer (Queen Mary College, London) and Dr. J. M. Ziman (Cambridge) then discussed the transport of heat and electricity in solids. Dr. Sondheimer emphasized the general validity of the Onsager reciprocal relations and showed how in some treatments of thermo-electric processes algebraic obscurity has led to methods of approximation which violate these relations, while Dr. Ziman discussed the variational principle used in the solving of transport equations. Dr. N. H. March (Sheffield) described the results of some measurements of the absorption of high-frequency radio waves in semi-conductors. Dr. K. W. H. Stevens (Nottingham) discussed the construction of bonding orbitals for the first co-ordination shell in face-centred and body-centred cubic metals, and Dr. R. Fürth (Birkbeck College, London) spoke on long-range order in crystals. An account of the recombination of current carriers in a semi-conductor was then presented by Dr. P. T. Landsberg (Aberdeen), and in conclusion Dr. G. A. P. Wyllie (Glasgow) discussed the problem of diffusion at low temperatures.

On the afternoon of November 20 an informal discussion was held on the teaching of theoretical physics. After short introductory talks by Prof. Bethe, Dr. D. ter Haar (St. Andrews) and Prof. Pryce on the teaching of theoretical physics in the United States, Netherlands and United Kingdom, respectively, two topics were discussed at some length: the amount of mathematics to be taught at the undergraduate level to students who will be proceeding to do research in theoretical or experimental physics; the amount of formal teaching in physics (and possibly mathematics) to be given to research students in experimental or theoretical physics. There was a very considerable degree of agreement on the following points: that students proceeding to do research in physics should have a thorough training in pure and applied mathematics, but that this presents difficulties in many British universities owing to the rigid structure of courses and examinations; and that there should be one year with considerable formal instruction at the beginning of the period of research, and that this should be received by experimental as well as theoretical physicists. This latter point was very forcefully put by several speakers, and its need was considered sufficiently great to outweigh the disadvantage that it might occasionally extend the Ph.D. training beyond the normal three years.

J. F. ALLEN

CHILDREN'S FILM FOUNDATION

THE Foundation was set up in 1951 as a result of the co-operative effort of the British film industry to ensure the production, distribution and exhibition of special entertainment films for children. It began its activities in October 1951 and, during this period, has become accepted, not only in Britain but also throughout the world, as an integral part of the British film industry. It is a non-profit-making organization and is financed by grants from British Film Production Fund, Ltd.

During the four years of its existence there has been time to set a standard for the content and quality of its films and to study their reception by audiences in Great Britain as well as overseas. The steady rise in the bookings is significant of the success of Children's Film Foundation films with the audiences for whom they are made.

Since in most situations the Foundation was starting completely anew, its first films followed the conventional pattern of the 'Western'. This was necessary because children are conventional in their tastes and do not accept innovations easily. It was enough, first of all, to introduce child actors in an English background without altering the simple 'good versus bad' technique. Generally, these pictures have proved highly acceptable.

The content of the films has been gradually changed to introduce ideas of achievement above and beyond the satisfaction of catching thieves or spies. Eight achievement stories have proved as popular as the conventional adventures. The fact that the films are placed with many different companies for production helps to give the pictures vitality and variety, which add to their value in children's programmes.

Although the Foundation has not yet been able to undertake any special research project, the reception of the films is carefully recorded and studied. Besides personal observations of audiences by the officers of the Foundation, a questionnaire, returned and filled in by cinema managers, provides valuable information. There appears to be little difference in taste and response between different parts of Great Britain; but some audiences, especially in the larger cities where they are more accustomed to film-going, like the story to develop quickly; rural audiences prefer a slower pace. Individual tastes vary enormously.

What clearly emerges is the excellent natural taste of children at the cinema. They are anxious to participate in the programme and their interest is lost only by weaknesses in production, acting and, above all, in the script.

It takes time to wear down the old-fashioned idea that children go to the cinema to be excited and stimulated by violent adult action; but it is dying out in Britain. The reports of cinema managers reflect the pleasure their audiences take in films that deal with children's problems and achievements. The only general suggestion for improving the films is the use of colour, which is costly.

The British Film Production Fund, Ltd., has made grants totalling £529,883 to the Foundation. Fundamentally, an entertainment film for children cannot be a low-priced production. Receipts from the distribution of films are now sufficient to pay for the cost of release prints, and the balance is paid to the British Film Production Fund. These receipts can never be large because admission prices to children's film shows are low. The Foundation's value to the industry and the community cannot be judged in terms of money since its primary object is to promote appreciative and intelligent film-going by youthful audiences. For this reason the British film industry as a whole supports the Foundation with an annual grant from the Fund.

FRESH WATER FROM SALT WATER

The production of fresh water from salt water must be one of the oldest technical problems. It is currently receiving a degree of widespread yet concentrated attention which surpasses anything previously devoted to it. The reasons for this are substantially the same the world over; chief among them is the fact that living standards are rising generally and that fresh-water consumption per head of population is a basic and reliable index to the standard of living of a community. As the degree of industrialization increases and living standards rise, so does the demand for water; reservoir capacity becomes inadequate, the drain on artesian wells increases (see *Nature* of Dec. 17, p. 1133). The consequence of the latter effect depends on the situation. In coastal areas it may lead to infiltration of sea water, in other areas to a raised salt content as the increased pumping lowers the level of the underground reserve. The possibility of demineralization must be considered in both cases. For alternative sources of water one may turn, depending on one's location, to new wells, which may themselves be brackish; to new reservoir capacity, if this is feasible and if the rainfall justifies it; to more or less long-distance pumping of supplies from distant sources; or in extreme cases to sea water. All these possibilities are likely to be expensive; the first may, and the last certainly will, involve demineralization procedures.

Some indication of the interest in these procedures has been described by D. J. Neville-Jones (*Research*, 8, No. 11; November 1955). Since some publicity was given to the United Kingdom participation in the Organization for European Economic Co-operation discussions on the subject a year or two ago, scores of inquiries have been received in London from places ranging from Norway to Australia, from Hong Kong to the Bahamas. The United Kingdom itself is interested, despite its notorious rainfall, because the inexorably increasing demand is leading to sea water infiltration in such areas as the Thames Estuary; it is becoming increasingly difficult to find uncontaminated alternative sources which do not involve expensive long-distance pumping. Germany has similar problems in the lower reaches of the Rhine. The Netherlands is concerned because, by the nature of its low-lying territory, sea water infiltration is always a likely problem. Australia and South Africa are developing territories in which sea water or other highly saline waters have to be considered. The rapid industrial development of the United States of America is leading to water shortages in the vast interior territories where in many cases only brackish water is available.

The problem is not simple to define, or solve. This will depend on a multiplicity of factors such as the availability and cost of energy sources, the mineral content of the raw matter and the purpose for which the fresh water is required, that is, the price which can be paid for it. Each case will have to be examined according to the local circumstances.

LABORATORY TECHNICIANS

A SUB-COMMITTEE of the Science Masters' Association has been considering the place of laboratory technicians in secondary schools and has now issued a report. The number of schools with laboratory technicians is far too small, and there is urgent need for more technicians to be employed. This is particularly important since the problem of the recruitment of laboratory technicians in schools is related to that of the shortage of science teachers. The sub-committee suggests, however, that the establishment of a national scheme for the provision of laboratory assistance on an adequate scale to all schools where a significant amount of science is taught is a problem in its own right.

The teacher without a laboratory technician finds himself with less time than he should have for his normal teaching duties, the planning of his work and for the development of new apparatus and techniques. He has no time for designing and arranging practical work which can be carried out by the pupils themselves, and all too frequently lessons become "chalk and talk". Such a wasteful use of the time of science teachers must be deplored.

The sub-committee considers that the duties of a school laboratory technician call for a considerable degree of skill and a good deal of training. Much work has been done by various organizations on the formulation of courses of study for laboratory technicians. For schools the most suitable of these is that leading to the examination for the Laboratory Technician's Certificate of the City and Guilds of London Institute. The facilities for study are expanding; twenty-four centres, mostly technical colleges, now offer courses of instruction recognized by the City and Guilds of London Institute, and the number of candidates entering for the examination has increased from eighteen in 1951 to ninety-six in 1954.

The sub-committee realizes that recruitment is one of the most difficult parts of the problem, but believes that science teachers would be able to encourage suitable boys and girls in their own schools to apply for the posts if they could assure their pupils that salary, prospects and promotion, good working conditions—hours, holidays, superannuation, sick pay—facilities for study, and status were such as to compete with those obtainable in other educational institutions and industry.

Suggestions are also made as to the scale of assistance which might be given to various schools, suitable scales of remuneration and the duties which could be performed by laboratory technicians.

DISTRIBUTION OF 8-AZAGUANINE IN THE NUCLEIC ACIDS OF *BACILLUS CEREUS*

By DR. R. E. F. MATTHEWS and DR. J. D. SMITH
Agricultural Research Council Virus Research Unit, Molteno Institute, Cambridge

8-AZAGUANINE can replace a proportion of the guanine residues in the ribonucleic acids of a variety of organisms, although the amounts incorporated are low, varying from less than 1 per cent to 3 per cent of the ribonucleic acid guanine[1]. We have now found that in *Bacillus cereus*, strain 569*H*, up to 40 per cent of the ribonucleic acid guanine may be replaced by 8-azaguanine when the latter compound is supplied during growth. This is comparable to the proportion of thymine which may be replaced by halogenated pyrimidines in the deoxyribonucleic acids of *Bacterium coli* and its bacteriophages[2]. This high level of incorporation has enabled us to study the distribution of 8-azaguanine in nucleic acid preparations, relative to the normal base, and to follow the course of 8-azaguanine incorporation during bacterial growth.

Aerated cultures of *B. cereus* 569*H* were grown at 36° on the following medium: vitamin-free casein hydrolysate, 10 gm.; KH_2PO_4, 3·5 gm.; $MgSO_4.7H_2O$, 0·51 gm.; $(NH_4)_2Fe(SO_4)_2.6H_2O$, 4·8 mgm.; in 1 l. water and adjusted to *p*H 7 with sodium hydroxide. 8-Azaguanine (40 μgm./ml.) was added at a suitable bacterial density and incubation continued for 2·5 hr. The cells were then chilled, washed and frozen. Ribonucleic acid was extracted with hot *M* sodium chloride after the cells had been defatted in ethanol and acetone. Some 10–20 per cent of the total polyribonucleotide content of the bacteria was extracted by this procedure. In other experiments treatment of the cells with water (3 hr. at 50° C.) yielded about 70 per cent of the total polyribonucleotide.

Preparations or fractions of ribonucleic acid were hydrolysed in *N* potassium hydroxide to mononucleotides, which were separated by paper chromatography in *iso*propanol–water–ammonia[3] followed by electrophoresis on paper at *p*H 1·7. The spots of guanylic and 8-azaguanylic acids were eluted and estimated spectrophotometrically. (On a larger scale, 8-azaguanylic acid can be separated from guanylic acid by ion-exchange chromatography on acid 'Dowex-50' resin.) Where estimates of total ribonucleic acid content of bacteria were required (for example, Table 1), alkaline digestion was carried out on whole bacteria after extraction with hot 50 per cent ethanol.

To study the relative distributions of 8-azaguanine and guanine along the polynucleotide chains, the ribonucleic acid was digested to completion with pancreatic ribonuclease. The final products of this hydrolysis are pyrimidine mononucleotides, polynucleotides consisting of chains of one or more purine residues terminated by a pyrimidine nucleotide residue, and purine nucleoside 2′ : 3′ cyclic phosphates[3]. The purine nucleoside 2′ : 3′ cyclic phosphates can only have occupied terminal positions in the ribonucleic acid chain adjacent to a pyrimidine residue[4]. The hydrolysis products were partially separated into a number of bands in paper using the *iso*propanol/water/ammonia solvent. In this solvent compounds containing 8-azaguanine move in the same position as the corresponding guanine derivatives. The bands, in order from the starting position in the chromatogram, were eluted and the fraction of guanine residues replaced by 8-azaguanine

$$\left[\text{molar ratio } \frac{(\text{8-azaguanine})}{(\text{8-azaguanine} + \text{guanine})} \times 100\right]$$

measured in each. This gave the relative distribution of the two bases in polynucleotides of decreasing size.

Table 1. REPLACEMENT OF 8-AZAGUANINE BY GUANINE IN THE RIBONUCLEIC ACID OF *B. cereus*

8-Azaguanine (50 μgm./ml.) was added to cultures 1 and 2 at zero time. After 30 min., guanine (25 μgm./ml.) was added to culture 2

Time after addition of 8-azaguanine	Molar ratio $\frac{(\text{8-azaguanine})}{(\text{8-azaguanine}+\text{guanine})} \times 100$ in bacterial ribonucleic acid		Relative amounts of ribonucleic acid in the cultures (based on D_{260} mμ of ribonucleotides after hydrolysis)	
	Culture 1	Culture 2	Culture 1	Culture 2
30 min.	13·5	13·5	2·62	2·62
60 min.	16·9	7·7	3·13	3·16
120 min.	28·2	4·0	3·76	5·66

Under conditions in which 20–23 per cent of the ribonucleic acid guanine was replaced by 8-azaguanine, enzymic hydrolysates of the bacterial deoxyribonucleic acid gave much-smaller amounts of a substance with properties of 8-azaguanine deoxyriboside (less than 1 per cent of the nucleic acid guanine). Extracts of the bacteria in hot 50 per cent ethanol contained substantial amounts of 8-azaguanosine and 8-azaxanthosine, but no free 8-azaxanthine, the principal metabolite of 8-azaguanine in mammals[5] and plants[6].

Ribonuclease digestion was carried out on ribonucleic acid preparations in which 20–23 per cent of the total guanine was replaced by 8-azaguanine. The fraction of guanine replaced by 8-azaguanine was found to increase as the average size of the polynucleotides decreased, varying from 17 per cent in the largest polynucleotides to 40 per cent in the dinucleotide region. The highest 8-azaguanine content was found in the band containing only the 2′ : 3′ cyclic phosphates of guanosine and 8-azaguanosine, where 68 per cent of the residues contained 8-azaguanine.

Some fractionation of ribonucleic acid preparations can be obtained by dialysis through 'Cellophane' in *M* sodium chloride, and by precipitation with increasing concentrations of ethanol at decreasing *p*H. Using these procedures, we found that polynucleotides of smaller average size contained a greater proportion of 8-azaguanine residues relative to guanine, and also a higher proportion of 8-azaguanine 2′ : 3′ cyclic phosphate terminal groups than the whole nucleic acid preparation.

Thus the nucleic acid preparations contained a number of shorter polynucleotide chains in which a higher proportion of the guanine residues has been replaced by 8-azaguanine. From the distribution of 8-azaguanine in ribonuclease digests, replacement appears to be least in the longer sequence of purine nucleotides in the ribonucleic acid chain and greater in the shorter sequences. The very high proportion of 8-azaguanosine 2′ : 3′ cyclic phosphate terminal residues in the nucleic acid could be explained by assuming that an 8-azaguanine residue in this position makes the further addition of nucleotide residues along the chain less likely. Alternatively, the 2′ : 3′ cyclic phosphate termination may have some special significance in ribonucleic acid turn-over.

The inhibition of bacterial growth by 8-azaguanine and the incorporation of the latter into ribonucleic acid may be annulled by supplying guanine. We have followed the disappearance of 8-azaguanine from the ribonucleic acid as the growth-rate is restored. 8-Azaguanine disappears much more rapidly than can be accounted for by dilution of existing ribonucleic acid by new ribonucleic acid without 8-azaguanine (Table 1). These results suggest either a rapid degradation and resynthesis of polynucleotides, or an exchange reaction in which bases can be replaced without breakdown of the polynucleotide chain.

We wish to thank Dr. Martin Pollock for the strain of *B. cereus* and the Medical Research Council Unit for Research in Antibiotics, Clevedon, for a large-scale preparation of this organism.

VARIATIONS IN THE AMOUNT OF FEULGEN STAIN IN NUCLEI OF PLANTS GROWN AT DIFFERENT TEMPERATURES

By Dr. L. F. La COUR

John Innes Horticultural Institution, Bayfordbury, Hertford, Herts

AND

Dr. E. M. DEELEY and Dr. J. CHAYEN

Wheatstone Physics Laboratory, King's College, London

It has long been known that growth at low temperature induces a linear differentiation in the metaphase chromosomes of certain plant species[1-3]. At temperatures ranging from −1° C. to +5° C., depending on the species, specific weakly Feulgen-staining segments appear which are constant in length and position. It was shown from a study in various plant species that such segments correspond to the condensed and frequently fused heterochromatic segments observable in telophase and interphase nuclei[1,2,4].

The weak reaction of heterochromatic segments in metaphases from plants grown in the cold was attributed to 'nucleic acid starvation'. This interpretation implies that low temperature, by retarding the synthesis of deoxyribonucleic acid, leads to the chromosomes entering mitosis with eu- and heterochromatic regions competing for a depleted supply of deoxyribonucleic acid. Antagonism to this view has grown with the recent wide acceptance of the concept that the amount of deoxyribonucleic acid per haploid chromosome set is constant[5,6].

The present study is part of an attempt to reinvestigate this phenomenon quantitatively by measuring Feulgen staining photometrically by means of a scanning densitometer devised by Deeley[7]. This was used in conjunction with a cell-crushing technique which enables measurements to be made at all phases of the mitotic cycle[8]. The accuracy of the scanning instrument has been demonstrated by a series of measurements made on Feulgen-stained sperm heads and cells of the onion root meristem, which show that the readings obtained are, in fact, proportional to the amount of stain present, to an accuracy of the order of ± 3 per cent for this type of material[7].

Plant species with and without detectable heterochromatin were investigated. Roots were removed and fixed after the potted plant had been kept at the control temperature (19°–20° C.) for at least four days. The plant was then subjected to the cold conditions; other roots were removed from it and

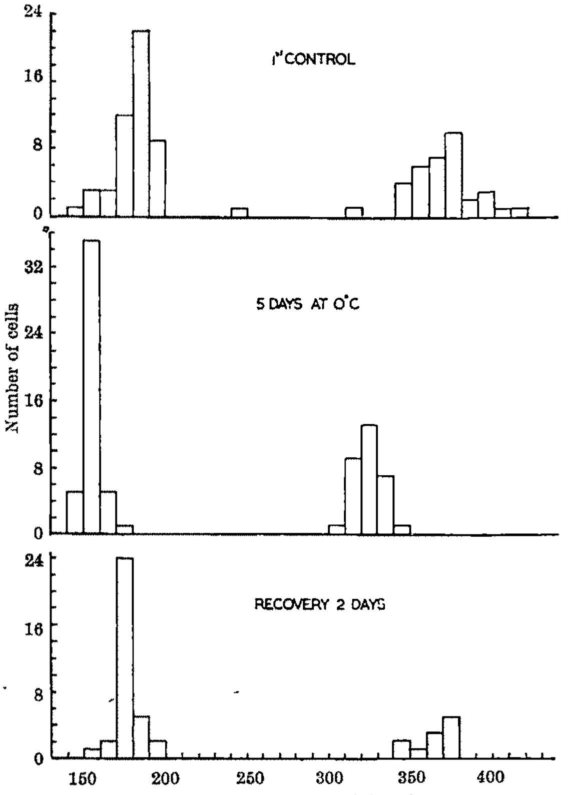

Fig. 1. Measurements of total Feulgen stain in mitotic nuclei of *Trillium grandiflorum*, showing the alteration in values obtained according to temperature conditions of plant growth. From root meristems of a plant kept at 19°–20° C. for four days, after five days at 0° C. and after return to 19°–20° C. for two days

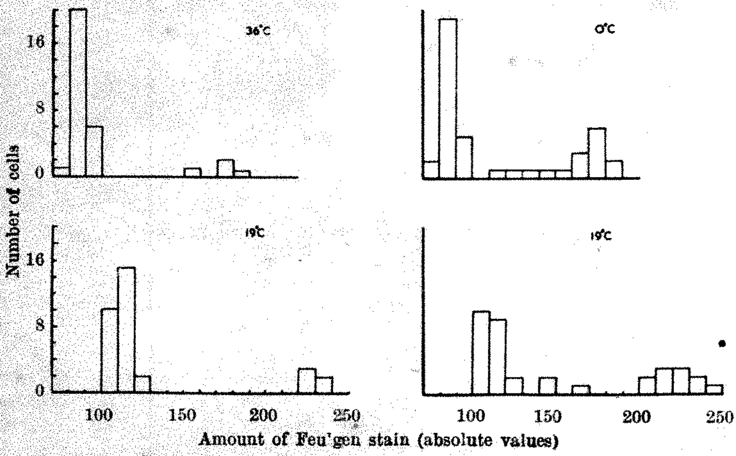

Fig. 2. Measurements of total Feulgen stain in mitotic nuclei from root meristems of *Scilla campanulata*, showing the similarity of values in two plants kept at 19° C. and the similar reduction obtained in them at two extremes of temperature

fixed at suitable intervals of time and the plant was returned to recover under the control conditions. It was thus possible to have controls from the same plant both before and after treatment.

Fixation, hydrolysis and staining were strictly the same for control and treated roots. Since all specimens from any one experiment were stained by the Feulgen reaction and measured at the same time, the first control roots had to be stored in 70 per cent alcohol in a refrigerator for a longer time than those grown in the cold. This was shown to have no effect on the final measurements, since identical results were recorded for the control roots taken before and after the cold treatment. All phases of the mitotic cycle were examined.

Six main facts have emerged from these initial observations. First, as recorded for animal tissues (cf. ref. 6), $2C$ and $4C$ values, depending on the stage of chromosome division and duplication of deoxyribonucleic acid, were obtained in nuclei from roots of plants kept at the control temperature. Thus telophase and most of the interphase nuclei had the $2C$ amount of Feulgen stain, whereas prophase, metaphase and some interphase nuclei contained twice this quantity; a few interphase nuclei had intermediate values. Secondly, smaller values of $2C$ and $4C$ were found in nuclei from plants kept for three to five days at low temperature. This reduction appeared in nuclei at all stages of mitosis irrespective of whether the species contained detectable heterochromatin or not (Table 1 and Fig. 1). Thirdly, the threshold temperature required for inducing these changed values varied with the species. This was clearly shown by the difference between *Scilla campanulata* and *S. sibirica*, where −1° and −6° C. respectively were required to reduce values for Feulgen staining (Table 1). Fourthly, comparable reductions to those in the root meristem were encountered in the resting nuclei of the differentiated zone. Fifthly, there was a return to normality in cells about to enter mitosis, and also in those of the differentiated zone, after cold-treated plants were returned to the control temperature (Fig. 1).

Finally, as shown in one experiment in which two plants of *Scilla campanulata* were used, high temperature can apparently cause a reduction of the value of C comparable to that obtained by cold (Fig. 2). It will be noted that the amounts of Feulgen stain in nuclei of roots taken from these two plants at the beginning of the experiment were identical.

We feel caution is required in interpreting these results. The simplest explanation would be that the decrease in the amount of Feulgen stain in the nuclei of roots grown at low temperature represented a true reduction of the deoxyribonucleic acid content. This would imply that the comparable loss in the resting differentiated nuclei represented the breakdown half of a deoxyribonucleic acid turnover cycle, the synthesis of the deoxyribonucleic acid being reduced. Until this interpretation can be confirmed by other means, however, it is necessary to recognize an alternative explanation, namely, that the change in temperature might alter the reactivity of the deoxyribonucleic acid to the Feulgen stain. No obvious mechanism can be suggested by which this could be effected by low temperature during growth and which would yet allow the deoxyribonucleic acid to be fully normal 48 hr. after the plant had been returned to control conditions. Furthermore, the fact that different temperatures were necessary to induce this effect in different species makes this interpretation appear somewhat unlikely.

We wish to thank Prof. J. T. Randall for his interest in the study and Dr. H. B. Fell for her helpful criticism of the manuscript. One of us (L. F. La Cour) is grateful for the provision of working facilities in the Wheatstone Physics Laboratory; E. M. Deeley and J. Chayen wish to acknowledge support from the Nuffield Foundation and the British Empire Cancer Campaign, respectively.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

An Electron Microscopical Study of the Histochemical Localization of Alkaline Phosphatase in the Cell Wall of *Chlorella vulgaris*

In algae it is considered that the oxidative assimilation of hexose follows the same glycolytic pathway as in higher organisms, and that these substances after dephosphorylation yield hexose phosphate, which may be used in polysaccharide synthesis, or enter the metabolic pool[1]. Enzymes that may take part in these processes have been shown by biochemical methods to be present on the cell surfaces of small organisms, such as yeast[2]. However, the limitations in resolution of the light microscope have made it difficult to demonstrate such enzymes histochemically, especially as regards their exact localization relative to the cell wall.

In this work, an attempt has been made to apply histochemical methods for observation with the electron microscope, thus increasing the possibilities of a more accurate localization due to the higher resolution of this instrument[3].

The material used in these experiments, *Chlorella vulgaris*, was transferred from agar slope to a liquid mineral medium and centrifuge-washed several times in distilled water. The centrifugate was then dispersed in Gomori's mixture for alkaline phosphatase, where it was incubated for periods of time ranging from 15 min. to 2 hr. It was then centrifuged in distilled water and treated with 0·5 per cent silver nitrate solution, centrifuge-washed in distilled water, fixed in 1 per cent osmium tetroxide vapour, dehydrated in graded alcohols and embedded in methacrylate. Ultra-thin sections were cut with the Sjöstrand microtome for examination in the electron microscope.

Material treated as above, up to the alcohols, was spray-mounted on 'Formvar'-coated grids and examined directly with the electron microscope.

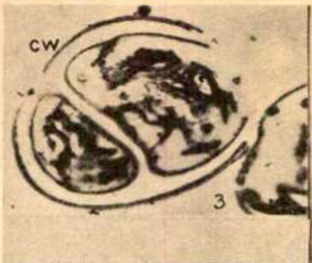
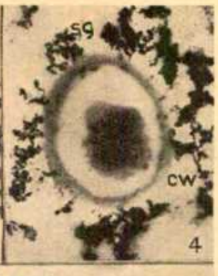
Fig. 2. Spray-mounted whole cell preparation. Incubated in Gomori's substrate for alkaline phosphatase. Positive reaction shows as dense granules of various sizes deposited on the cell wall. × 4,000. *sg*, silver granules





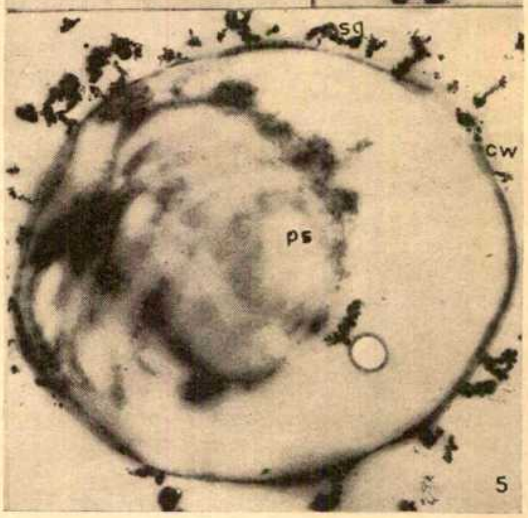


Fig. 3. Ultra-thin specimen section of control specimen. Note small number of granules on the cell wall. × 4,000. *cw*, cell wall

Fig. 4. Ultra-thin section of specimen incubated in Gomori's substrate for alkaline phosphatase. The positive reaction shows as a dense aggregate of silver granules partly attached to the cell wall. × 4,000. *cw*, cell wall; *sg*, silver granules

Fig. 5. Ultra-thin section of specimen incubated in Gomori's substrate for alkaline phosphatase. The positive reaction appears as an aggregate of dense granules of silver attached to the cell wall. × 7,000. *cw*, cell wall; *sg*, silver granules; *ps*, protoplasmic structures

Controls were run by treating the tissues in the same way except that the glycerophosphate was omitted from the incubation mixture. Sections were also made from material fixed in osmium tetroxide vapour, dehydrated in alcohols and embedded in methacrylate.

The von Kóssa method for showing up the calcium phosphate formed as a result of enzymatic action suggested the detection of silver phosphate at the sites of reaction; silver phosphate is readily visible in electron micrographs as a dense granular precipitate.

Fig. 1 shows the electron micrograph of untreated spray-mounted specimens. Fig. 2 shows the electron micrographs of spray-mounted specimens incubated in Gomori's mixture. The positive reaction is indicated by dense granules, presumably of silver phosphate, unevenly distributed on the cell wall. The cell wall appears as a denser band at the edges. However, this picture does not show the relationship between the silver precipitate and the cell structures.

Fig. 3 shows an ultra-thin section of the cell of the control material. Very few granules, of whatever origin, are present. This might be due to the unspecific deposit of the silver present in the control incubation medium. Figs. 4 and 5 are electron micrographs of ultra-thin sections of cells incubated in Gomori's medium. Here the positive reaction is marked by dense granules attached to the outer surface of the cell wall. These granules appear as particles of various sizes and in different degrees of aggregation. There also appears to be some reaction in relation to the structures present in the cell interior.

The histochemical demonstration of alkaline phosphatase has been subjected to critical experimental analysis by Danielli[4]. The rather short period of incubation and the fact that the incubation was carried out prior to fixation provide the optimum conditions for minimizing artefacts. The present results tend to confirm previous biochemical determinations which have indicated the presence of enzymes on the cell surface in other organisms[2].

In our preparations the apparent lack of contact, in many places, between the silver precipitate and the cell surface, can perhaps be explained by the fact that the material was centrifuged with forces up to 7,000 *g* at least eight times after the precipitate had been formed. The heavy metal particles, under these conditions, would be expected to separate somewhat from the cell wall. As can be seen in the preparations of spray-mounted, unsectioned specimens, the particles of silver seem to be more closely associated with the cell wall. This may be accounted for by the fact that no centrifugal force was applied after the silver precipitate was formed. In considering the weak reaction observed inside the cell, it is necessary to bear in mind that the cells have been incubated intact in the Gomori substrate, and that the possibility exists that the substrate might not have been able to penetrate the cell membrane into the protoplast structures.

The pure culture of *Chlorella vulgaris* used was obtained through the courtesy of Dr. G. E. Fogg, Botany Department, University College, London.

This work was carried out at the Anatomiska Institutionen, Karolinska Institutet, Stockholm, while we were guests of F. S. Sjöstrand, to whom our thanks are due.

Analysis of Crystalline Hæmoglobin Derivatives by Paramagnetic Resonance

The investigation of single crystals of hæmoglobin derivatives by paramagnetic resonance can give two distinct types of information. First, the actual resonance conditions and the resultant *g* values associated with the electronic transitions will yield details on the orbitals involved in the chemical binding of the central iron atom. Secondly, the angular variation of the *g* values enables an accurate determination to be made of the orientation of the hæm and porphyrin planes with respect to the external crystalline axes. Although the structure of the rest of the molecule cannot be analysed directly in this way, detailed information on the orientation of the hæm planes can be combined with X-ray measurements[1] to calculate the polypeptide chain directions and similar factors. It would appear that the determination of the hæm plane orientations by paramagnetic resonance is much more accurate than that by any other method so far applied.

The main experimental limitation in such an investigation is the relatively small size of the crystals available, and for this reason all the measurements are made at 20° K. with a low-temperature resonator[2] and at frequencies of 25,000 Mc./s. or 36,000 Mc./s. When studying angular variation the electromagnet is rotated around the resonator, and the field positions of the absorption line plotted against angle of rotation. The first derivative studied in detail was whale acid-met myoglobin, as this was available in the form of large single crystals. The results obtained from this are a good illustration of the two types of information that can be obtained by paramagnetic resonance.

First the magnitude of the *g* value associated with the single electronic transition was found to vary from a $g_{\perp} = 5\cdot95 \pm 0\cdot05$ to a $g_{\parallel} = 2\cdot00 \pm 0\cdot01$. As previously noted[3], the occurrence of such a wide *g* value variation can be explained by assuming that $S = \pm \frac{5}{2}$ and that the lowest doublet is $S_Z = \pm \frac{1}{2}$ with a zero-field splitting to the other spin doublets much greater than that of the microwave quanta (> 2 cm.$^{-1}$). This splitting is far larger than that encountered in other ferric salts, and shows that the charge distribution on the surrounding atoms has a much greater effect than in normal ionic binding.

Secondly, the angular variation of the *g* value can be used for locating the axis through the iron atom perpendicular to the hæm plane, since this direction corresponds to the $g_{\parallel}$ of 2·0. This determination is based on the fact that, with axial symmetry, the *g* value at any angle θ from the axis is given by $g^2 = g_{\parallel}^2 \cos^2\theta + g_{\perp}^2 \sin^2\theta$, or, in the case of these derivatives, $\sin^2\theta = \frac{1}{8}\left(\frac{g^2}{4} - 1\right)$. By rotation in the *ab*, *bc* and *ac* crystallographic planes, the direction of the minimum *g* value in these planes can be located, and from its magnitude the angle which the parallel axis makes with the particular crystallographic plane can be calculated. Sperm-whale myoglobin crystallizes in two different types *A* and *B* [1,4], and the results of measurements on both types are given in Table 1, in the form of the direction cosines for the axis through the iron atom perpendicular to the hæm plane.

Table 1

Crystal type	Crystal symmetry	Direction cosines of axis *L*	*M*	*N*
A	$P2_1$	0·89	0·36	0·28
B	$P2_12_12_1$	0·13	0·95	0·29

The acid-met derivative is only one of many that can be investigated in this way, and these large loosely packed organic crystals have the advantage that individual crystals can be directly converted to other derivatives without loss of form. Thus an acid-met crystal can be immersed in a solution of sodium azide for a controlled time and then removed with half the crystal as an azide derivative and half still as an acid-met derivative. This technique is very useful since the previously analysed spectrum of the latter can then be used as a check on the orientation and g-value symmetry of the new derivative. In this way it can be shown that the g value of the azide derivative varies from a maximum $g_\perp$ of $2{\cdot}8 \pm 0{\cdot}05$ to a $g_\parallel$ of $1{\cdot}70 \pm 0{\cdot}05$, with considerable distortion of axial symmetry. The occurrence of a single electronic transition with g values spread across the free-spin value indicates that the binding is of the d^2sp^3 type, leaving one unpaired spin with some orbital admixture, similar to the case of potassium ferricyanide[5].

Further measurements are in progress on other derivatives and with hæmoglobin and myoglobin of different species, to obtain as much detailed information as possible on the binding of the iron atom and the orientation of the hæm planes. We would like to thank Dr. J. C. Kendrew for supplying the single crystals.

Spectrophotometric Method for the Estimation of Vitamin K_3

Reddy and Srinivasan[1] have described a method for the estimation of vitamin K and vitamin K_3 which is slightly different from that of Novelli[2]. During the course of our investigation on the biosynthesis of vitamin K in moulds, we found that the method of Reddy and Srinivasan was not suitable for determining microquantities of vitamin K. It was observed that, on standing, the intensity of the colour at the junction of the two layers increases, with the result that the intensity of colour is not uniform throughout the layer. In the present communication, we wish to describe a modified method which can be used to estimate vitamin K in the range 2–30 μgm.

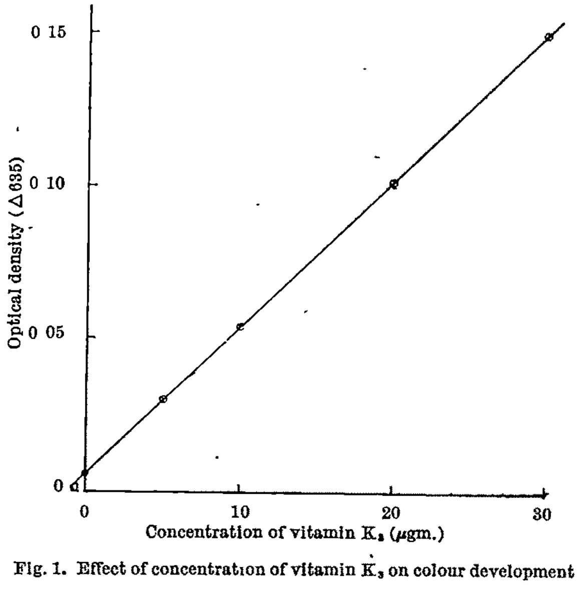

Fig. 1. Effect of concentration of vitamin K_3 on colour development

Vitamin K_3 solution (2–30 μgm.; 2-methyl-1,4-naphthoquinone) was shaken with 0·5 ml. of ethyl alcohol and to this was added 0·1 ml. of a saturated solution of 2 : 4-dinitrophenyl hydrazine in 2 *N* hydrochloric acid. After 10 min., 0·25 ml. of 20 per cent sodium carbonate was added and shaken well until the green colour appeared. 3 ml. of amyl alcohol, 1 ml. of ethyl alcohol and 1 ml. of water were added, shaken thoroughly and kept for 5 min. for the salts to go down. The amyl alcohol layer was taken and the density read at 635 mμ in a Beckman model *DU* spectrophotometer (1 cm. light-path). The colour obtained in this method is stable for 10 hr. Distilled ethyl and amyl alcohol were used throughout this investigation. Fig. 1 gives the relation between the optical density (Δ 635 and the concentration of vitamin K_3).

Details of the application of this method to estimate microquantities of vitamin K in moulds will be described elsewhere.

The 'Queen-Substance' of Honeybees and the Ovary-inhibiting Hormone of Crustaceans

In the course of work on the social organization of honeybee communities[1], it has been found that worker honeybees obtain a substance ('queen-substance') from their queens which, if obtained in sufficient quantity, inhibits development of their ovaries and the production of further queens. It will also, under experimental conditions, inhibit ovary development in worker ants (*Formica fusca*) (unpublished work, C. G. B.). A similar hormone has been shown to inhibit ovary development in decapod crustaceans[2]. These substances appear to be similar in several respects. Thus both are stable to heat and to acids but less so to alkalis, soluble in acetone and alcohol, both are active, at least under certain conditions, when taken orally, and both serve to inhibit development of the ovary and related phenomena.

We decided, therefore, that it might prove of interest to administer honeybee queen-substance to prawns and also the ovary-inhibiting hormone of prawns to bees. The results of preliminary experiments are now available.

The queen-substance from a single mated queen honeybee (*Apis mellifera* L.) was extracted in alcohol. This extract was mixed with water, a little palmitic acid added, the *p*H adjusted to 6·2 and the alcohol and excess water distilled off. A control emulsion was prepared in the same way starting with alcohol alone.

Three groups, each consisting of twelve female prawns, were used. The prawns in group I remained intact and received no injections. The eye-stalks of the prawns in group II were severed, thus removing

Table 1

Condition and treatment of animals	Mean weight of ovaries (mgm.)	Histological condition of ovaries
(I) Intact; received no injection	4·90±0·65	All fully regressed; no commencement of vitellogenesis
(II) Eyestalks removed; control emulsion injected	17·67±3·39	All with well-developed yolk-droplets. One ovary full of yolk and showing dark green, ripe colour
(III) Eyestalks removed; honey-bee queen-substance injected	6·56±0·72	Some yolk-droplets present in a few cells in each ovary

the ovary-inhibiting hormone, and on the following day each of these prawns received an injection of 0·08 ml. of the control (alcohol) emulsion. The prawns belonging to group III had their eyestalks removed, and on the following day 0·08 ml. of the experimental (alcohol + honeybee queen-substance) emulsion was injected into each. This experiment was carried out at the time of year when most ovary-inhibiting hormone is present in the eyestalks of prawns and their ovaries are fully regressed. In such circumstances, removal of eyestalks normally leads to rapid ovary development.

One week after injection the surviving prawns—nine in each group—were killed and their ovaries weighed and examined histologically (Table 1).

The results show that removal of the eyestalks of the prawns forming the controls (group II) resulted in development of their ovaries and that, since there is a significant difference ($P < 0·001$) between the degree of ovary development in the prawns in group II and III, a single injection of honeybee queen-substance has produced a strong but incomplete inhibition of ovary development.

In the reciprocal experiment, twenty sinus glands—the organ in the eyestalks of crustaceans in which the ovary-inhibiting hormone is stored[2]—were removed from female prawns (*Leander serratus*) and their contents were dispersed by means of a Potter homogenizer in 67 per cent sucrose syrup. This syrup was then incorporated in a pollen-candy mixture and fed continuously to newly emerged bees kept in a cage at 31° C. and supplied with drinking water. Another group of newly emerged bees, the controls, were kept similarly but fed on a pollen-candy mixture without the addition of sinus-gland contents.

After nineteen days it was determined whether the ovaries of each bee had developed or had remained undeveloped as they would have done in the presence of a queen (Table 2).

It is clear that there is a highly significant difference ($P < 0·001$) in the degree of development of the ovaries of the bees of these two groups, and it appears that the sinus-gland extract of prawns has inhibited ovary development in worker honeybees.

Table 2

	Treatment	No. of bees with ovaries developed	No. of bees with ovaries undeveloped
Control group	Fed pollen-candy mixture	30	4
Experimental group	Fed pollen-candy mixture + prawn sinus-gland contents	15	17

To the similarities which we have observed between the queen-substance of honeybees and the ovary-inhibiting hormone of prawns may now be added a reciprocity of action. It seems probable that these two substances are the same or related compounds, possibly steroids, and occur in a number of arthropods.

An Erythrocyte Sphering Factor in Rat and Mouse Plasma

When suspensions of many types of mammalian red cells in saline media are examined between a glass slide and coverslip, the cells change their shape from biconcave disks, through a stage of crenation, to spheres[1]. This change is associated with the removal or inactivation of an anti-sphering factor normally present in plasma albumin[2].

Recently, Trotter[3] in this laboratory has demonstrated the great importance of contamination of glassware by some substance, possibly a fatty acid, present on human skin. A single handling of a clean cloth used for wiping slides or coverslips contaminates both the cloth and the glassware and causes sphering. If the contaminated glassware is flamed, however, red cells retain their disk-like form. This finding makes it possible to observe the action of sphering agents without the presence of plasma or albumin. We have found that the plasma of several common varieties of laboratory rats appear to contain a substance which will cause sphering of saline suspensions of human cells between flamed slides and coverslips. This is in marked contrast to the behaviour of the plasma of the ox, pig, sheep and man as well as purified bovine or human plasma albumin, which not only have no sphering action but on the contrary prevent sphering on unflamed slides and protect the cells against substances such as sodium oleate, which cause sphering. In fact, the spheres observed in rat plasma can be changed back into disks by the addition of sufficient human plasma. The sphering activity of rat plasma is quite high; one part of rat plasma diluted with four parts of 2 per cent human albumin causes complete sphering and one part in twenty causes crenation of all cells and some sphering.

Rat plasma causes sphering of the cells of several other species including the rabbit and cat. There is no sphering action on rat cells, or on mouse cells, though the latter may become cupped. Human plasma does not cause crenation or sphering of rat cells, though cupping may occur (in our experience cupping seems to be a common reaction of the red cells of one species to the plasma of another; but we found no reference to this in the literature). Plasma from common laboratory mice behaved similarly to that from the rat, though the activity was rather less. Plasma from the vole, wild Orkney mouse, hamster and rabbit all caused crenation, but not complete sphering, while guinea pig plasma seemed to be quite inactive. The effect is thus not universal among rodents. We have sometimes observed that the sphering activity appears to increase if the plasma is left to stand for some hours at room temperature. Sphering activity has not been observed in the plasma of other common animals though the number investigated is comparatively small.

Indirect evidence suggests that the sphering agent may be a fatty acid. It is possibly significant that Robinson *et al.*[4] have found that rat plasma contains an active lipolytic system which brings about the dissolution of chylomicrons with the release of free fatty acids. No explanation can yet be offered of why the rat cells do not become spherical in their own plasma.

We wish to thank Dr. D. S. Robinson for useful discussions and the Rockefeller Foundation for financial assistance. This work was aided by a personal grant (F. M. G.) from the Medical Research Council.

A Method for determining the Duration of Action of the Cardiac Glycosides

The determination of the duration of action of the cardiac glycosides has depended mainly on toxicity experiments which require large numbers of animals. The Hatcher method[1] depends on the difference between the usual lethal dose of a suitable cardiac glycoside and the actual dose required to kill at various times after the administration of the cardiac glycoside under test. Another method developed by Hauptstein[2] makes use of the relationship between the rate of infusion and the toxic dose of a cardiac glycoside; the decrease in toxicity with slow rates of infusion indicates the degree of elimination (detoxification and excretion). Data on the duration of action are also available from clinical records, where the criterion for the persistence of cardiac activity after the administration of a cardiac glycoside can be electrocardiographic changes such as alteration of the *T*-wave or decrease in heart-rate, or the therapeutic effect, although this is difficult to evaluate precisely.

A property of the cardiac glycosides has recently been described by Rand, Stafford and Thorp[3], which can be adapted for the study of the duration of action of cardiac glycosides and related compounds, particularly short-term changes seen with certain rapidly metabolized drugs of this group. The action of injected adenosine on the guinea pig heart (a transient period of partial heart-block) is markedly potentiated by doses of cardiac glycoside which alone are too small to have any observable effect on the electrocardiograph. The degree of potentiation appears to depend on the amount of digitalis drug available to the heart.

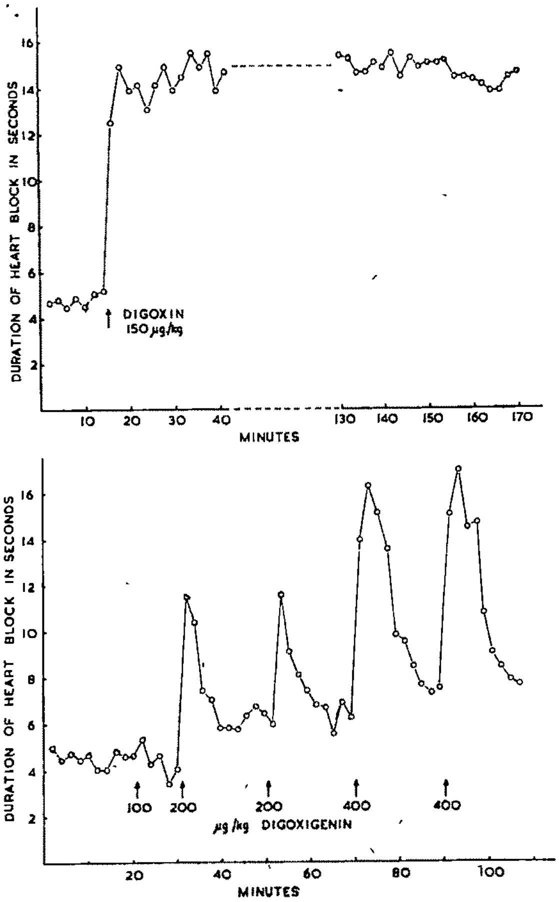

Fig. 1

Injections of adenosine are made at regular intervals, and then a dose of the cardiac glycoside under test is given. The change in duration of the period of heart-block produced by adenosine injections gives an indication of the activity of the cardiac glycoside. (The technical details have been described by Rand *et al.*[3]). With a single injection of digoxin, the potentiation of the adenosine effect persists for longer than three hours with no indication of any decrease, whereas a single injection of digoxigenin produces only a transient increase in the duration of the adenosine heart-block. Typical experiments are shown graphically in Fig. 1. It can be seen that a higher dose of digoxigenin is required to produce the same degree of potentiation as digoxin, reflecting the lower toxicity of this compound in the guinea pig. The rate of dissipation of digoxigenin can be calculated as the time for the response to adenosine to return to its previous level after giving the digoxigenin. From the results given in Fig. 1 the rate of elimination of digoxigenin is approximately 1·5 mgm./kgm./hr. for the high dose and 1·0 mgm./kgm./hr. for the lower dose. Hoffman and Lendle[4] found a value of 1·0–2·0 mgm./kgm./hr. for the elimination of digitoxigenin in the guinea pig using a slow infusion method.

A study of the rate of elimination of a number of other cardiac glycosides and genins and their synthetic derivatives is in progress, together with experiments on the role of hepatic and renal mechanisms in their elimination.

We are indebted to Prof. R. H. Thorp for his interest and encouragement during the course of this work, and to Mr. S. E. Wright, of the Pharmacy

Section, for supplying a chromatographically pure sample of digoxigenin.

Biosynthesis of Fatty Acids by Seeds of *Ricinus communis*

So far, the biosynthesis of fatty acids in plant material seems to have received little attention; in this connexion we notice especially the communications of Newcomb and Stumpf[1]. We have now taken up similar researches on seeds of *Ricinus communis* var. *sanguineus*. The seeds were germinated in moist sand at 30° C. in darkness, the cotyledons sliced with a thin razor blade by freehand into sections ± 0·5 mm. thick, and aliquots incubated in water and substrate in a Warburg apparatus for 6 hr. at 30° C. After incubation the slices were rinsed and extracted with a mixture of ethanol–ether (3 : 1); evaporation *in vacuo* leads to pure castor oil. After saponification, the non-saponifiable material was extracted with petroleum-ether. The fatty-acid fraction was acidified, extracted several times and the combined ether-fractions dried and evaporated.

An aliquot of the fatty acids was subjected to chromatographic fractionation by the method of Howard and Martin[2]; ricinoleic acid, because of its alcoholic function, had a different solubility and passed the column as a $C_8 - C_{10}$ fatty acid (see also J. Boldingh[3]). With acetate as substrate, the respiratory quotient was ± 0·85; with propionate it was a little higher; without substrate, it was lower than 0·85. The latter fact is due to a higher oxygen consumption. The concentration of the substrates was 0·01 *N*.

Although incubation of the slices with ^{14}C-1 acetate (± 0·15 mgm.) reveals an important conversion of the ^{14}C-1 acetate to carbon dioxide, a considerable part was metabolized and incorporated into fatty acids. This fact confirms again that acetate is an important precursor of the fatty acids in seeds.

Separation of the acids by urea complexes[4] showed that the ricinoleic acid fraction, containing 70 per cent of the total fatty acid content, possessed practically no radioactivity; the remaining fraction, containing the saturated and unsaturated fatty acids, was highly active. Fractionation of radioactive castor oil by the method of Howard and Martin confirmed these results and proved that the ^{14}C-1 acetate was incorporated mainly into the C_{18} fatty acid (Table 1).

Table 1. FRACTIONATION OF CASTOR OIL (^{14}C-1 ACETATE AS SUBSTRATE)

Fatty acid	Specific activity (counts/min.)	Total activity	Acetate incorporated × 100
Ricinoleic acid (72·2%)	0·6	180·4	0·39
C_{12} acid (3·0%)	10·8	136·1	0·30
C_{14} acid (2·6%)	41·8	451·4	0·98
C_{16} acid (4·5%)	48·7	920·4	2·0
C_{18} acid (17·7%)	126·8	9,357·9	20·4
Non-saponifiable material	550·0	715·0	1·5

Table 2. FRACTIONATION OF CASTOR OIL (^{14}C-1 ACETATE AND GLUCOSE AS SUBSTRATE)

Fatty acid	Specific activity (counts/min.)	Total activity	Acetate incorporated × 100
Ricinoleic acid (64·9%)	0·7	203·8	0·44
C_{12} acid (2·3%)	15·0	157·6	0·34
C_{14} acid (5·1%)	59·7	1,380·4	3·01
C_{16} acid (12·9%)	250·1	13,668·5	29·83
C_{18} acid (14·3%)	79·4	5,257·3	11·47
Non-saponifiable material	818·0	1,554·2	3·4

Addition of glucose (conc. 0·01 *N*) to the ^{14}C-1 acetate substrate reduced respiratory quotient during several hours of the experiment, by diminution of the exhaled carbon dioxide, but it stimulated the incorporation of acetate into the fatty acids at a considerable rate. Fractionation of castor oil carried out in this way shows that: (1) the percentage of stearic acids and ricinoleic acid is lowered in favour of the C_{14} and C_{16} acids. (2) The radioactivity is transported to the C_{16} fraction (see Table 2).

The non-saponifiable material possessed, contrary to the results of Newcomb and Stumpf, considerable radioactivity. This indicates that acetate might play a part in the biosynthesis of phytosterols.

Our results on the influence of glucose may be explained by assuming that glucose acts as an acetate 'sparer'. The question remains open whether glucose is an active precursor of glycerol, and whether the removal of the fatty acids, as triglycerides, from the metabolic pool, is limited by the amount of glycerol available.

These experiments illustrate also the possibility of free metabolites influencing the lipid metabolism of germinating seeds.

A Synthetic Growth Medium for the Trypanosomid Flagellate *Strigomonas (Herpetomonas) oncopelti*

BIOCHEMICAL studies of the Trypanosomidae have been delayed by the difficulties encountered in cultivation and maintenance of many species. Up to the present time, only one member of this family (*Herpetomonas culicidarum*) has been cultivated in a defined medium[1], and this was of a degree of complexity comparable to that required by the most exacting bacteria. The present communication describes a simple synthetic medium which will support the growth of the parasitic flagellate *Strigomonas oncopelti*; this trypanosomid, first isolated in bacteria-free culture by Noguchi and

Table 1. A SYNTHETIC GROWTH MEDIUM FOR THE PARASITIC FLAGELLATE *Strigomonas oncopelti*

Pyridoxine hydrochloride	1·0	KCl	0·42
p-Aminobenzoic acid	1·0		
Biotin	0·01		
Trace metal solution*	10 ml.		

Glass-distilled water to 1 litre

Initial *p*H value, 7·2. Medium sterilized by autoclaving at 10 lb pressure for 10 min.

* Trace metal solution: $MgSO_4.7H_2O$, 20·0 gm.; $FeSO_4$, 0·5 gm.; $ZnSO_4.7H_2O$, 0·5 gm.; $MnSO_4.3H_2O$, 0·5 gm.; $CuSO_4.5H_2O$, 0·5 gm., made up to 1 litre in *N*/10 sulphuric acid.

Tilden[2] in 1926, is parasitic in the digestive tract of Hemiptera and in latex plants. Lwoff[3] reported that *Strigomonas oncopelti* could be cultivated in alkaline hydrolysates of silk or in certain peptones if these were supplemented with thiamine; in contrast to other trypanosomids, it does not require hæmatin as a growth factor.

The nutritional requirements of *Strigomonas oncopelti* have been determined in a synthetic medium according to the general method of Gladstone[4]. A complete medium which would support the growth of the flagellate was prepared containing twenty-one amino-acids, eight growth-factors, purines, pyrimidines, glucose, ammonium chloride, sodium and potassium phosphates and trace metals. Further batches of media were prepared to test the effect of omission of the above components either singly or in groups. Cells to be used as inocula in growth tests were grown in the complete medium for 24 hr. at 25° C. and were washed three times in the medium to be tested; a standard inoculum of 2 × 10^5 cells/ml. growth-medium was used in all cases.

Results showed that the amino-acid requirement of this organism could be satisfied by methionine alone; adenine was also required for growth in addition to the growth factors thiamine and nicotinamide. In a glucose – salts medium containing these additions, growth was slow, the organisms having a mean generation-time of more than 24 hr.; the further addition of biotin, pyridoxin, pantothenic acid and *p*-aminobenzoic acid more than doubled the growth-rate, and cells reached a final density of about 4 × 10^7/ml. (≡ 0·4 mgm. dry weight cells/ml.). *Strigomonas oncopelti* has now been maintained on this medium for more than six months, being subcultured at intervals of three to four days; the detailed composition of the medium is given in Table 1. This is the simplest medium yet recorded for the growth of a parasitic flagellate, and it is interesting to note that *Strigomonas oncopelti*, although a parasite of Hemiptera and latex plants, is considerably less exacting nutritionally than the free-living ciliate *Tetrahymena pyriformis*[5].

So far as I am aware, there is no account in the literature of the cultivation of any member of the Trypanosomidae on solid media, Protozoa of this group usually being cultivated on complex diphasic media. *Strigomonas oncopelti* grows readily on a solid medium prepared by adding 0·7 per cent (w/v) agar to the synthetic medium described; discrete colonies are visible after four days incubation at 25° C. and cultures can be kept for three to four weeks without loss of viability.

The development of a synthetic medium for *Strigomonas oncopelti* permits for the first time a detailed study of the biosynthetic capabilities of an actively growing trypanosomid. Experiments using the synthetic medium described, supplemented with tracer amounts of acetate labelled with carbon-14, have shown that 50 per cent of the acetate carbon is fixed in the lipid fraction of logarithmically growing cells, 35 per cent is located in the cell protein (the use of methyl- and carboxyl-labelled acetate indicates that both carbons are utilized for the synthesis of glutamic and aspartic acids, alanine, threonine, tyrosine, lysine, arginine, valine, proline, phenylalanine and the leucines), and the remaining 15 per cent is distributed equally between the acid-soluble cell constituents and the nucleic acid fraction. These and other results, which will be reported in detail elsewhere, are similar to those obtained by McQuillen and Roberts[6], who studied the utilization of acetate for synthesis in *Escherichia coli*, and may be interpreted in terms of the Krebs tricarboxylic-acid cycle functioning in actively growing *Strigomonas oncopelti*.

Resolution by means of a Micro-organism of Racemic Diaminosuccinic Acid and Determination of its Configuration

THE chemical structure of diaminosuccinic acid is analogous to aspartic acid, asparagine, C_4-dicarboxylic acids and the other biologically important substances. The acid, however, has not yet been found in Nature, and so has never been fully investigated. In 1925, racemic acid was resolved into its antipodes by Kuhn[1], through the morphine salt of N,N′-dibenzoyl diaminosuccinic acid; $[\alpha]^{20}_{D} = -18·9°$ (10 per cent hydrochloric acid). Suzuki and Suzuki[2] found, during the course of an investigation on the behaviour of micro-organisms towards the acid, that *Micrococcus ureae* was capable of growing on a medium containing the racemic acid as the sole source of nitrogen, and that about half the amount of racemic acid always remained even after full growth. From these observations the authors considered that the micro-organism preferentially assimilated one of the two optical isomers, and that a non-utilizable antipode could perhaps be isolated from the medium.

(1) *Synthesis of Racemic Diaminosuccinic Acid.* The acid was prepared by the reduction of dioxytartaric acid phenylosazone in the following manner, which was a modification of Farchy's method[3], since, in our hands, it gave more satisfactory results. A powder of 100 gm. of the osazone was resolved in 1 litre of 2 per cent sodium hydroxide with 1 kgm. of cracked ice, and 4 kgm. of sodium amalgam (2·5 per cent) was added to the solution; the mixture was stirred for 1 hr. At the end of the reaction, 167 gm. of 30 per cent sulphuric acid was slowly added (the temperature rising to 40° C.), and after stirring for

an additional hour, the mixture was filtered. The filtrate was decolorized with the continuous extraction of ether, and when it was acidified with sulphuric acid to *p*H 2, the meso-isomer precipitated. After the precipitate was filtered off, the filtrate was adjusted to *p*H 5 with sodium carbonate. It was necessary for the complete precipitation of the racemic acid to keep the solution for a week at 0° C. The crude preparation was purified by recrystallizations from aqueous hydrochloric acid as well as Farchy's method, and dried over phosphorus pentoxide *in vacuo*; the yield was 13 gm. The racemic acid contained one mole of water.

Analysis. Calc. for $C_4H_8O_4N_2.H_2O$: N, 16·86; found: N, 16·90 per cent. Melting point of N,N′-dibenzoyl-diaminosuccinic acid, 162° C. R_F values by paper chromatography (ascending method): *n*-BuOH/AcOH/H_2O (4 : 1 : 1), 0·04; phenol saturated with water, 0·11.

(2) *Culture and Extraction.* *Micrococcus ureae* was incubated at 30° C. with shaking in the following medium: distilled water, 1 litre; glucose, 10 gm.; sodium citrate, 2 gm.; dipotassium hydrogen phosphate, 1 gm.; ammonium chloride, 0·5 gm.; DL-diaminosuccinic acid, 0·5 gm.; crys. magnesium sulphate, 0·1 gm.; sodium chloride, 0·1 gm.; potassium dihydrogen phosphate, 0·1 gm.; *p*H adjusted to 7·0 with sodium hydroxide. After 24 hr., the culture solution was added with trichloracetic acid, and deproteinized by centrifuging. The supernatant was adjusted to *p*H 5 and concentrated to one-twentieth of the first volume by vacuum distillation. Diaminosuccinic acid was obtained as crude crystals by keeping the concentrated solution in an ice-box for one week. It was purified by recrystallizations from aqueous hydrochloric acid and dried over phosphorus pentoxide *in vacuo*; the yield was 40 per cent of racemic acid. Its nitrogen content, melting point of dibenzoyl derivative and R_F values were identical with those of the racemic acid.

(3) *pH-Change of the Specific Rotation.* The rotatory power of this preparation of diaminosuccinic acid was measured in solutions of sodium hydroxide and hydrochloric acid of various concentrations. Table 1 shows that the specific rotation was at a maximum in neutral solution, and successive additions of acid or alkali to it resulted in a lævorotatory shift. It is well known that the specific rotation of amino-acids varies decidedly with the *p*H of the solution, and that unnatural amino-acids (D-configuration) show maximum dextrorotatory power in neutral solutions, whereas natural amino-acids (L-configuration) show maximum lævorotatory power in these solutions[4]. Therefore it is concluded that the configuration of this antipode belongs to the *D*-series.

Table 1. SPECIFIC ROTATION OF D-DIAMINOSUCCINIC ACID AT VARIOUS SODIUM HYDROXIDE OR HYDROCHLORIC ACID CONCENTRATIONS

Moles of sodium hydroxide or hydrochloric acid per mole diaminosuccinic acid in the solution		Specific rotation* $[\alpha]_D^{20}$
NaOH	65·1 38·9 19·4 10·8 1·1	− 2·84 − 4·96 − 9·04 − 13·40 + 5·47
HCl	4·7 9·8 20·1 47·0 250·0	+ 32·20 + 16·70 − 0·65 − 4·36 − 16·80

* Measured by a Landolt-type polarimeter (0·01°) with 1-decimetre tube.

(4) *Racemization of D-Diaminosuccinic Acid by Benzoylation.* In order to measure the specific rotation of N,N′-dibenzoyl-D-diaminosuccinic acid, it was benzoylated by Kuhn's method using benzoyl chloride and sodium bicarbonate; the reaction was run at 25° C. for 2 hr. The specific rotation of the benzoyl derivative thus prepared (melting point,

$$162° \text{ C.) was } [\alpha]_D^{20} = +0\cdot019\,\frac{100}{1\cdot004 \times 1\cdot693} = +1\cdot12°.$$

Since the specific rotation of the same substance obtained by chemical resolution[1] was + 106·5°, it is evident that our preparation had been racemized through this procedure.

Separation of Unstable Oxidation Intermediates of Cysteine

THE recent emergence of new bio-functional thiol compounds (coenzyme-A, lipoic acid) has revived interest in the series of compounds which represent oxidation-levels intermediate between —SH and —SO_3H.

We therefore wish to record an observation made some time ago in connexion with paper chromato-

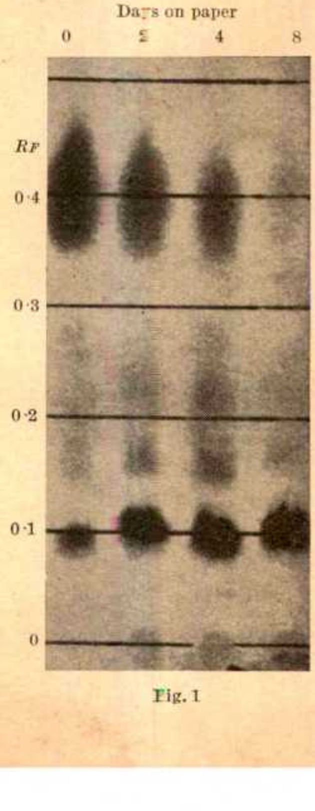

Fig. 1

graphic experiments[1], which suggests a simple technique for visualization and separation of unstable oxidation products. In order to evaluate the stability of cysteine in paper chromatography, we applied, on different days, to *S. & S. 589 GR* paper four spots of 10λ, each of which contained 80μ of cysteine hydrochloride in $3\,N$ hydrochloric acid in 50 per cent formic acid. When the last spot had dried, the paper was developed with phenol/*iso*propanol/water[1] and treated with ninhydrin. Fig. 1 shows the results. From left to right, the spots have been 'ageing' on the paper for 0, 2, 4 and 8 days before development. This is accompanied by a steady decrease of cysteine (R_F 0·4) and a steady increase of cystine (R_F 0·1, and probably in non-ionized form at R_F 0). In addition, intermediates, that is, compounds which pass through a time-maximum, are seen at R_F 0·16 and 0·23, and perhaps at 0·27. Discreteness of the spots and absence of tailing indicate that they represent a record of oxidative events occurring on the fibre surface in the 'dry' spots, and that little, if any, changes occur during the solvent-run. The possibilities of detecting and isolating unstable oxidation intermediates by these means are obvious.

Insect Mobility and Design of Field Experiments

Recent papers have stressed two of the problems that arise in the design of field trials when insecticides are employed. McKinlay[1] noted that the protection of a crop afforded by the use of insecticide may be partially vitiated by re-invasion of insects from adjacent unsprayed plots. The converse of this situation was mentioned by Joyce[2], who pointed out that in the Sudan Gezira "the insect regime on unsprayed cotton may have been [so] affected by the wide-scale application of insecticide upon surrounding cotton".

A population of a mobile species is conceived to be in dynamic balance, numbers lost by emigration being replaced by immigration. When the distribution of a population has been affected by the application of insecticides, these two processes operate side by side to modify the environment in which sprayed and unsprayed crops grow. An important consequence of this modification can be the diminution of differences of yield expected between sprayed and unsprayed plots. By recolonization, the yield of a sprayed plot may be diminished; but following the action suggested by Joyce[3], the yield of a control plot may secondarily be increased by a drain of insects from the control to the sprayed plots.

Entomological opinion in the Sudan Gezira leans to the view that areas sprayed with DDT act as traps into which the nymphs and adults of *Empoasca libyca* de Berg migrate and die. In this way, populations upon control plots are reduced. By local usage, this postulated movement of jassids from unsprayed areas is termed an 'interplot effect' and connotes the ability of a plot to modify the character of the insect population upon an adjacent cropping area.

Recolonization by jassids of a previously sprayed area at Tokar as an example of interplot effect has been examined by Goodman (unpublished results). The inward movements of *Empoasca* nymphs from unsprayed cotton could be detected two weeks after spraying, though it is probable that continuous invasion occurred at all times after this date. The invasion was noticed first at the periphery of the sprayed plot, and the subsequent rates of build-up of nymphal populations were significantly correlated (P = 2 per cent) with the distance of the sampling station from the sprayed/unsprayed interface.

The influence of sprayed areas in reducing populations of jassids infesting adjacent unsprayed cotton was elucidated recently. The experimental unit consisted of two observation rows of *X*1730*A* cotton surrounded on each side by five rows of the same variety. These outer ten rows were sprayed on a number of occasions, but the jassid counts were made only upon the unsprayed central observation rows, which were protected during spraying by temporary hessian screens. There were ten replicated subplots for each treatment, each subplot having an area of 350 sq. metres.

In Table 1 are shown the total numbers of jassid nymphs counted from fifty leaves per subplot on eight occasions between October 13 and November 27, 1954. Using the log n transformation, analysis of variance of the total nymphs counted per plot showed that significant differences of population existed between the numbers of nymphs on the control subplots (that is, observation rows surrounded by unsprayed cotton), and the numbers counted on observation rows surrounded by cotton sprayed one or more times.

Table 1. TOTAL RECORDED POPULATION OF NYMPHS ON 50 LEAVES PER SUBPLOT FOR 8 OCCASIONS

Surrounds sprayed	Total population on observation rows per subplot (log means)
Control	2·3299
1×	2·0975, 2·1830
2× : 3×	1·9229, 1·9762 : 1·9354, 1·8786
4×	1·7095, 1·7764, 1·7855

Least sig. diff. P = 5 per cent (as log) 0·1358.

That is to say, the presence of plots sprayed with DDT adjacent to unsprayed areas of cotton significantly reduced the infestation of cotton jassid upon these untreated plots. Four applications of DDT produced a greater effect upon populations on nearby unsprayed areas than did fewer applications.

This evidence is important because, where large areas of cotton are sprayed each year, as in the Sudan Gezira, the apparent benefit from DDT spraying may be considerably less than expected; indeed, may fail to reach significance level, owing to the operation of interplot effects, although other tests may show that the destruction of the cotton jassid significantly improves yields.

The interplot effect demonstrated in the case of the cotton jassid has wide implications; indeed, the concept appears in different guises and has many applications in applied entomology. Thus Pearson[4] notes both the beneficial and disadvantageous aspects of this effect in respect of the protection against *Heliothis armigera* Hb. afforded by well- or ill-timed successions of maize and leguminous crops. De Bach and Bartlett[5], in North America, showed that sprayed citrus trees trap and poison immigrant *Vedalia*

104 reflexions should be sensitive to changes in the c/a ratio, since one reflexion depends on the values of the a-axes and the other mainly on the value of the c-parameter. These measurements show that the c/a ratio is larger at 95° K. than at room temperature.

As a more quantitative check, the curves shown in Fig. 1 were extrapolated to 95° K. The values so obtained for a and c, 4·944 A. and 13·599 A., respectively, agree very well with the results for the 226 and 21·10 reflexions from the diffractometer measurements at that temperature.

I thank Dr. Donald A. Edwards for making the low-temperature measurements, and Dr. J. Samuel Smart for helpful discussions.

Colour Centres in Metaphosphate Glass

IN a recent communication[1], Basu states that we have attributed the coloration of metaphosphate glasses, induced by X-rays, to the activating influence of the metal (aluminium, barium, silver, etc.) in the glass, and that his results with sodium metaphosphate glasses show that '*F*-centres' can be produced without these activators. In the references to our work cited by Basu[2,3], the point is made that radiophotoluminescent centres having certain specific properties are connected with the presence of silver in potassium–barium–aluminium metaphosphate glass. It is clearly shown, we believe, in the publications from this Laboratory[3-5] that a visible coloration is produced upon X-irradiation of the above silver-free base glass, two broad bands appearing with peaks at about 420 mμ and 530 mμ. These colour centres were not attributed to any 'activating' influence of the aluminium, barium or other metallic constituents of the glass.

WHEN writing my communication published in *Nature* of August 5, I had to rely on abstracts of Mr. Schulman's papers; this was responsible for my misrepresentation of Mr. Schulman's point of view. The information now supplied by Mr. Schulman is very interesting, for it appears that none of the bands observed in my system is present in the silver-free base studied by Schulman, and his 420-mμ band is completely absent in my system. This shows that a more critical study of this system is necessary before these bands can be assigned definitely to various trapping centres, although I have made some tentative assignment from the study of glass systems of different composition.

Reproduction of Potato Root Eelworm during the Winter in a Potato Clamp

IN early March 1955, a freshly opened clamp of King Edward potatoes was inspected at Little Downham, Isle of Ely. It was observed that cysts of potato root eelworm (*Heterodera rostochiensis*) had already formed on the roots of many tubers which had sprouted and grown in the clamp. The cysts were in various stages of development. Some were white and others had turned yellow and contained fully embryonated eggs. It was estimated that there were more than a hundred cysts on some root systems. The wet autumn of 1954 had made lifting conditions very difficult and much damp soil had been clamped with the potatoes. Under these conditions root growth had been induced, and it is certain that the larvæ must have invaded the roots within the clamp and completed their development during the winter.

The field, on the black fen, was sampled to determine the level of infestation. The infestation was severe—5·24 viable cysts per gm. and 1,072 eggs per gm. of air-dried soil.

When a field is lightly infested with potato root eelworm, the clamp site will quickly become contaminated, as some soil will be deposited there from all parts of the field during harvesting operations. In addition, a clamp site often supports a high population of volunteer potatoes which will help to build up the eelworm numbers. If reproduction occurs within the clamp, the level of infestation may be increased still further, even though it is possible that many larvæ do not reach maturity under these conditions.

Migration of Nematodes

THE relationship between hydrostatic pressure-deficiency and the migration of larvæ of the beet eelworm, *Heterodera schachtii* Schmidt, has been described previously[1]. It was shown that larval mobility was low in sand in which water was confined to the points of contact of sand particles. It was suggested that more critical experiments would be needed to determine whether there was an optimum pressure-deficiency for eelworm migration.

Accordingly, an apparatus (Fig. 1) was devised for examining this problem further, using the stem eelworm *Ditylenchus dipsaci*. *a*–*b* is polythene tubing,

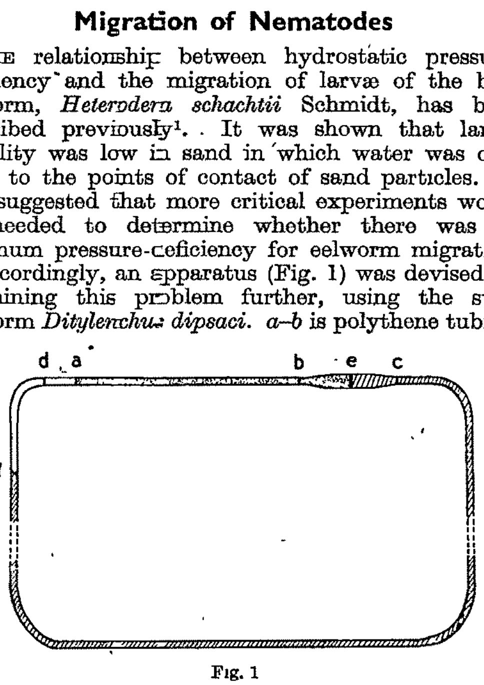

Fig. 1

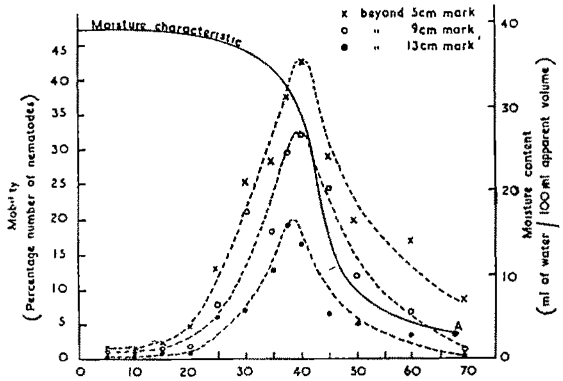

Fig. 2

18 cm. long and of 0·5-cm. bore ; *b–c* is a glass tube containing a sintered-glass plate *e* ; *c–d* is a loop of polythene tubing of the same bore as *a–b*, and *d–a* is a glass connecting tube. Sand of particle-size 200–400μ extends from *a* to *e*, and water extends from *e* to *f*. By varying the distance of the water meniscus *f* below the tube *a–b*, the hydrostatic pressure-deficiency in the sand can be regulated. A series of tubes was set up in this manner giving a range of pressure-deficiencies. About 10,000 eelworms in a drop of water were introduced into the sand at *a*. Previous experiments showed that the eelworms were carried from the end of the tube as the drop of water became distributed in the sand. However, no eelworms were carried more than 1 cm. in this way. After 16 hr., each polythene tube was cut into 1-cm. lengths and the number of eelworms in each section counted. The distribution of eelworms along each tube was thus obtained.

The results (Fig. 2) have been expressed graphically to show the percentage number of eelworms which were recovered beyond the 5, 9 and 13 cm. marks from the inoculation site (*a*, Fig. 1), at each pressure-deficiency. The moisture characteristic of the sand is also shown. As pressure-deficiency increases from 5 to 40 cm. of water, there is a corresponding rise in migration of eelworms. For pressure-deficiencies greater than 40 cm. of water, there is a decline in migration. The pressure-deficiency for maximum mobility of *D. dipsaci* in sand of particle size 200–400μ is thus 40 cm. of water, the point at which about 25 per cent of the pore space is occupied by air.

Observations suggest that *D. dipsaci* moves farther in a thin water film than when it is in a thick layer of water. Further investigation of this problem is needed ; but if this statement is accepted as a hypothesis, then it is possible to account for the relationship between eelworm mobility in sand and deficiency of hydrostatic pressure as follows. At low pressure-deficiencies the pore spaces are filled with water, air–water interfaces will be absent and mobility will consequently be low. Under these conditions, aeration will also be at a minimum and this may also inhibit active migration. As pressure-deficiency increases, air appears in the pore spaces, and movement in the resulting water films is consequently increased. In addition, increased aeration may also contribute to the general effect of increased mobility. With further increases in pressure-deficiency a point is reached when the continuity of the water film is broken. At this stage (point *A* on the moisture characteristic, Fig. 2), the nematodes are probably confined to water at the points of contact of sand particles. Progression through the sand will then entail a bridging of the air gap between water droplets, and this would inhibit migration in spite of high aeration.

Experiments with *Heterodera schachtii* indicate that there is a similar relationship between the distribution of water in sand and migration. Work is at present in progress on the factors influencing the migration of this species in soil.

I am indebted to the Sugar Beet Research and Education Committee for providing facilities for carrying out this work.

Prevention of Toxæmia of Late Pregnancy in Sheep

DISABILITY and death in ewes during late pregnancy and the puerperium due to toxæmia of pregnancy (twin-lamb disease) are an important cause of loss to the sheep industry in most of the principal sheep-raising countries of the world[1].

Although many observers have stressed the importance of a change in the nutrition of polytocous ewes during late pregnancy in the etiology of the disease[2], my recent observations in Britain suggested that excessive gain of weight in early pregnancy might render ewes particularly prone to develop toxæmia if they were subjected to changes in nutrition or other stresses in late pregnancy[3]. This hypothesis has been used empirically as the basis for a system of antenatal care designed to control the occurrence of the disease, which is meeting with considerable success. As the annual loss from the disease has been estimated to be £1–£2 million in Britain and £10 million in the Commonwealth[4], it seemed desirable to make some preliminary results available now.

The relevant details of consecutive lambings in some fifty lowland flocks in England and Scotland are set out in Table 1. The striking reduction in the number of cases of toxæmia and in the number of deaths in groups 1 and 2 is immediately apparent. The results in group 3 in 1955 would have been much better but for one large flock which had a mortality-rate of 12·6 per cent caused by failure to follow instructions and make adequate adjustments in the feeding during a spell of severe weather. If this flock is excluded, the figures, shown in brackets in the table, are excellent. These results are most encouraging, particularly in view of the maintenance of the average litter-size and indeed its increase in 1955 in two of the three groups to more than 1½ lambs per ewe. As it has proved impracticable to obtain results from unsupervised flocks which might serve as a control, this study should obviously be continued for a longer period to take into account the well-known natural fluctuations in the occurrence of the disease from year to year ; but the fact that such a low rate of attack was attained in 1955 when the disease in many neighbouring flocks was more prevalent than usual (Parker, W. H., personal communication) suggests that the general hypothesis may be substantially correct.

Table 1. DATA RELATING TO THE OCCURRENCE OF TOXÆMIA OF LATE PREGNANCY IN CERTAIN BRITISH LOWLAND SHEEP FLOCKS, 1953–55

Group	Year of supervision		No of flocks	No. of ewes at risk*	Average litter size†	Pregnancy toxæmia			Attack-rate per 1,000 ewes at risk*	
						Total cases	Died	No. of flocks affected	Morbidity	Mortality
1 (Pedigree Suffolk folded flocks in England and Scotland)	1st	1953	28	4,138	1·39	66	62	7	16·0	15·0
	2nd	1954	27	4,055	1·29	31	13	8	7·6	3·2
	3rd	1955	31	4,463	1·54	13	11	9	3·0	2·5

	2nd	1955	5	2,211	1·63	61	54	5	27·6	24·4
			4‡	1,781	1·62	7	3	4	3·9	1·7

* Ewes at risk is the number of ewes put to ram less those barren, those aborting (before 135 days of gestation) and those lost by accident and death, excepting those dying of pregnancy toxæmia.

† Average litter size is the ratio of the total number of lambs carried by the ewes at risk, that is, the total number of live and dead born lambs plus the lambs carried by ewes dying of pregnancy toxæmia, divided by the number of ewes at risk.

‡ Excluding one flock (see text).

The system of ante-natal care, which has been used with individual modifications in all the flocks, has aimed at restricting the gain of weight of the ewes during early pregnancy, while ensuring good gains during late pregnancy. As soon as the ewes are known to be pregnant, their nutriture has been maintained unchanged as far as possible by control of the food intake, either by varying the size of the fold or the amount of grazing allowed. About six to eight weeks before lambing is due (depending on the weather), the food intake has been increased, either by allowing access to improved grazing or more usually by feeding supplements of corn, hay, etc. A common method has been to give a concentrate feed containing about 10 per cent of good-quality protein, commencing with ¼ lb. a head a day and increasing to 2 lb. a day for the last fortnight before parturition; during periods of severe weather, these amounts may be increased. At the same time, provision has been made for plenty of exercise, and any cases of the common ailments such as contagious foot-rot treated at once. Further details of these measures have been given elsewhere[5].

A Bathynellid from the New World

THE species of the syncarid family Bathynellidae are typical representatives of the subterranean freshwater fauna. There are three known genera, *Bathynella* from Europe, *Parabathynella* from Europe, Madagascar, Malaya and Japan, and *Thermobathynella* with the species *adami* Capart from the Belgian Congo and *leleupi* Delamare Deboutteville and Chappuis from Lake Tanganyika[1,2].

A locality on the American continent can now be added. In 1954 S. Gerlach undertook a voyage to Brazil, assisted by a fellowship of São Paulo University and the Deutsche Forschungsgemeinschaft. On January 13, 1955, he discovered a bathynellid species at Icoaraci, about 17 km. north of Belém (Parà), by the bank of the River Parà about 80 km. upstream from the ocean. The beach of Icoaraci consists of pebbles, gravel and clay. A little pit had been dug at a distance of about 1 m. from the shore. The subsoil water appeared 10–15 cm. below the beach surface. The water did not smell brackish, but Dr. H. Sioli states that at least in the dry season of the year the water at Icoaraci and up to Belém used to be brackish.

The sample contained three specimens of Bathynellids, some oligochaetes, polychaetes and acari, one harpacticoid copepod and numerous nematodes. Most of the nematodes belong to the species *Onchulus longicaudatus* Cobb. This species has been described "from soil about the roots of living plants imported from Brazil into the United States"[3], so the actual habitat of the type specimen is unknown. But it is an interesting fact that *Onchulus nolli* Goffart, the only other representative of the genus, may be considered a truly stygobiont European species, found exclusively in subsoil freshwater biotops and sometimes even together with *Bathynella natans* Vejdovsky[4].

The new bathynellid species from Brazil is a representative of the genus *Thermobathynella* Capart, the second antenna consisting of five joints and extremities lacking on the eighth thoracic segment. It can be distinguished from *Th. adami*[5] and from *Th. leleupi*[2] by the first antenna, which consists of five joints instead of six, and by the fact that epipodites are lacking on the first two pairs of thoracopods. In the arrangement of the setæ on uropods and furca the new species is similar to *Th. leleupi.*

A comprehensive description will be published in *Kieler Meeresforschungen*.

Corrosion and Shell Composition in Barnacles

It was originally suggested by Darwin[1] that the susceptibility to disintegration of the shell of the common littoral barnacle, *Chthamalus stellatus* (Poli), was a consequence of its high content of organic matter. This suggestion has been accepted by many authors; but there appears to be no analysis to support the contention.

The organic matter and calcium content of the shells of several common barnacles, namely, *C. stellatus*, *Balanus balanoides* (L.), *B. crenatus* Brug. and *B. balanus* (L.) Da Costa, have been determined. In each case, fifty well-formed individuals of about 10 mm. rostro-carinal diameter were used. *Chthamalus stellatus* was taken from the upper level of the shore, *Balanus balanoides* and *B. crenatus* from mussel shells near low-tide level and *B. balanus* from material dredged at 20 m. The soft parts were removed, and the shells thoroughly cleaned by brushing; in the case of *Chthamalus stellatus* it was not possible to remove all the adherent unicellular green algae. The shells were then dried at 105° C., the inorganic material dissolved in dilute hydrochloric acid and the residual organic matter separated, washed and dried. Calcium was determined in the solution by a double precipitation as oxalate followed by titration with standard potassium permanganate solution. The results are shown in Table 1.

Table 1
(All values as percentage oven dry material)

Species	% Organic fraction	% Calcium as $CaCO_3$ of inorganic fraction
C. stellatus	2·1	91·1
B. balanoides	1·1	91·8
B. crenatus	0·6	90·7
B. balanus	0·8	93·4

It is evident that while the calcium content remains very uniform, *C. stellatus* contains a relatively larger organic content. However, when the difficulty of removing the unicellular green algae from this species is remembered it may be doubted whether the larger organic content at such a low value of the total is, *per se*, responsible for the increased susceptibility to corrosion. It is suggested that this is rather a function of the structure of the compartments than the quantity of organic material. Although the walls of *C. stellatus* have no parietal tubes they are permeated by numerous fine tubules. The latter are also present in the compartments of *Balanus balanus* (which undergoes corrosion) together with a number of small irregular pores. The presence of these tubules near the surface of the outer lamella could weaken the wall and allow corrosion to take place. In less-corrodible species quite large parietal tubes may be present, but these are flanked by solid calcareous wall. In support of this suggestion, it may be pointed out that in some species of *Tetraclita* notable for their extreme corrosion, although tubules are absent, the walls are permeated by several rows of thin-walled parietal tubes so that in section the compartments have a honeycomb appearance; the solid character of the wall and its resistance to corrosion are thereby destroyed.

Dimorphism in the Portuguese Man-of-War

The Portuguese man-of-war (*Physalia*) occurs in two forms which are mirror images of one another but otherwise identical. Under the influence of the wind, one form (left-handed) moves to the right of the downward direction, the other (right-handed) to the left.

Woodcock[1] was the first to attempt to relate these facts to wind and water movements. He observed that a large majority of specimens from the North Atlantic and Gulf of Mexico were right-handed, and sailed to the left of the downwind direction. To explain this, Woodcock formed a hypothesis which required in part that southern hemisphere forms be mirror images of northern hemisphere forms, and sail to the right of the downwind direction. An examination of museum specimens seemed to show that there was, in fact, a preponderance of right-handers from the southern hemisphere (19 out of 22). Fontaine[2] observed, however, that the forms driven ashore on the southern coast of Jamaica were always left-handers. The prevailing wind was from the east.

In the Canary Islands this year we observed that forms driven into the harbour at Arrecife, which lies on the eastern coast of Lanzarote, were always left-handers when the wind came from the east or north-east. On one occasion when the wind came from the south-west, right-handers were driven in.

It seems probable from Fontaine's and our own observations that the proportion in which the two forms are found varies in particular localities not according to the hemisphere but according to the position of adjacent land and the direction of the wind.

We tentatively put forward the view that in each brood of *Physalia* the two forms are produced in rough equality, and that this has survival value in that it obviates the stranding of the whole brood in any one set of circumstances. The early development of *Physalia* is little known so it is impossible to say whether or not the two forms are genetically different.

Crude experiments were made by one of us to ascertain the speed and angle of drift of *Physalia*. In light-to-moderate breezes the following results were obtained with the aid of a spherical glass float, a chart and landmarks inside the mole at Arrecife. Towards the end of flood-tide on April 15 the speed of drift over the tide was 20 m./min. On April 16 at slack-water the courses taken by a number of animals moving across the wind varied from 34° to 42° to the right of the downwind direction. A boat sailing into the wind makes more forward than lateral way, but *Physalia*, though pointing up to the wind, makes much lateral and slight stern way.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 13

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Lord Halsbury: "The Semantics of Determinism".

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Power Supplies to Electrical Laboratories". Opening Speaker: Dr. P. F. Soper.

Tuesday, February 14

University College, London (in the Anatomy Theatre, Gower Street, London, W.C 1), at 1.15 p.m.—Mr. R. T. Green: "Psychology and the Search for a Model".*

Zoological Society of London (in the Mappin Refreshment Pavilion, Mappin Terrace, Zoological Gardens, Regent's Park, London, N.W.1), at 5 p m.—Scientific Papers.

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—H.E. Mrs. Vijaya Lakshmi Pandit, High Commissioner for India in London: "The New India" (Sir George Birdwood Memorial Lecture).

Imperial College (in the Main Chemistry Lecture Theatre, Imperial Institute Road, London, S.W 7), at 5.30 p.m.—Prof. D. G. Christopherson: "Reflections on the Education of Engineers in a University" (Inaugural Lecture).

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. F. Coales and Mr. A. R. M. Noton: "An On-Off Servomechanism with Predicted Change-Over".

Royal Society of Medicine, Experimental Medicine Section (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Discussion on "Clinical and Experimental Studies with Radioactive Iron". Opening Speakers: Dr. L. F. Lamerton, Dr. Mary Smith and Dr. M. S R Hutt.

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. F. B. Shepherd: "Manufacture of Phosphorus".

Society for Analytical Chemistry, Physical Methods Group (in the meeting room of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Polarography"

Wednesday, February 15

Royal Society of Arts (at John Adam Street, Adelphi, London W.C.2), at 2 30 p m.—Mr. L. H. Bedford: "The Arithmetic of the Musical Scale".

Eugenics Society (at Manson House, 26 Portland Place, London, W.1), at 5 p m —Mr. Frederick Osborn: "Galton and Mid-Century Eugenics" (The Galton Lecture).*

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S W 7), at 5 p.m —Mr. D. H. Sadler: "The Abridged Nautical Almanac"; Mr. P. Beeham: "Navigating Without Instruments", Dr. J. G Porter: "The Earth Satellite Project".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Discussion meeting on "Measurement of Water Vapour in the Stratosphere".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. P. E. Hart and Dr. S. J. Prais: "The Analysis of Business Concentration—a Statistical Approach".

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S W.1), at 5 30 p.m.—Prof. J. Ivon Graham (Dunedin): "Fuel Conditions in New Zealand with special reference to the Coal Industry".*

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. D. Lacy: "Cell Inclusions in Vertebrate and Invertebrate Cells by Light and Electron Microscopy".

Aslib (at the Royal Society of Arts, 8 John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. D. McKie: "Sources of Information in the History of Science".

Institution of Electrical Engineers (at the Central Hall, Westminster, London, S.W 1), at 6 p.m.—Mr. B. L Metcalf: "Coal Mining Electrically" (Faraday Lecture).

British Psychological Society (joint meeting of the Education and Industrial Sections, in Room 173/4, Institute of Education, Malet Street, London, W.C.1), at 6.30 p.m.—Prof. L. J. Cronbach: "Technical Recommendations of the United States Committee on Test Standards".

Royal Institute of Chemistry, London Section (at the Institute of Metals, 4 Grosvenor Gardens, London, S.W.1), at 6.30 p m.—Dr. B. C. Saunders: "Some Properties and Reactions of the Enzyme Peroxidase".

Thursday, February 16

Physical Society, Low Temperature Group (at the Royal School of Mines, London, S W.7), at 4 p.m.—Dr. H. Ziebland: "Transport Properties of Liquefied Gases".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 4 30 p.m.—Dr. W. A. Sledge: "Observations on the Fern Flora of Ceylon"; Dr. P. Van Royen: "The Netherlands Botanical Expedition 1954–55 in New Guinea".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m —Mr. A. H. Cook, Mr. H. Meyer and Mr. W. P. Wolf: "A New Method of Correlating the Magnetic Temperature Scales of Paramagnetic Salts below 1° K.", Mr. C. D. Clark, Mr. R. W. Ditchburn and Mr. H. B. Dyer: "The Absorption Spectra of Natural and Irradiated Diamonds".

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. P. F. Whelan and Dr. D. J. Brown: "Particle-bubble Attachment in Froth Flotation"; Mr. P. A. Williams: "The Identification and Valuation of Decomposed Columbite-bearing Granites of the Jos-Bukuru Younger Granite Complex, Nigeria".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. G. W. Whitehead: "Suspension Theorems".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. L. J. Kastner: "Some Engineering Problems" (Inaugural Lecture).*

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Technical Authorship and Illustration".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Discussion on "Sicklæmia". Opening Speaker: Dr. A. C. Allison.

Friday, February 17

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Scientific Papers.

Saturday, February 18

Biochemical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Symposium on "The Structure of Nucleic Acids and their Role in Protein Synthesis".

British Psychological Society (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. M. L. Johnson: "Exploring in Group Discussions the Factors Affecting Scientific Judgment".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist, Basic grade (with a B.Sc. degree with honours in biochemistry or chemistry or equivalent qualification)—The House Governor, The General Hospital, Birmingham 4 (February 18).

Lecturers (2) in Statistics—The Secretary, The University, Aberdeen (February 18).

Entomologist (under 30, with a degree with entomology as a special subject) in the Department of Research and Specialist Services, Ministry of Agriculture, Federation of Rhodesia and Nyasaland, for duties which will include laboratory and field research on insects and their near relatives, extension and advisory work mainly on agricultural entomology, but including some medical and veterinary entomology—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (February 24).

Assistant Astronomer in the Government Observatory, Perth, Western Australia, for duties mainly relating to research work in positional astronomy and photographic astronomy—Public Service Commissioner, 60 Barrack Street, Perth, Western Australia (February 29).

Organic Chemist (Scientific Officer grade) at the Long Ashton Research Station—The Registrar and Secretary, The University, Bristol 8 (February 29).

Assistant Agricultural Economist (graduate in economics and/or agriculture-horticulture) at Newton Abbot—The Registrar, The University, Bristol (March 1).

Assistant Experimental Officer (preferably with a degree in botany or agricultural botany) for work on cereal diseases—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (March 1).

Assistant Lecturer or Demonstrator in Pathology, and an Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (March 3).

Assistant Lecturers (2) in Zoology—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (March 3).

Deputy Librarian—The Registrar, The University, Sheffield (March 3).

Morphologist (with a university honours degree in botany and research experience) in the Division of Forest Products, Section of Wood and Fibre Structure, Commonwealth Scientific and Industrial Research Organization, South Melbourne, Victoria, Australia, to carry out investigations on cell differentiation and fibre structure with special reference to lignification—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C.2, quoting 290/437 (March 3).

Research Officer (with a university honours degree in science or agricultural science, and preferably with postgraduate research experience) in the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Australia, to undertake surveys and field pedological studies of Australian soils—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (March 3).

Lecturer in Physics—The Registrar, King's College, Strand, London, W.C.2 (March 9).

Lecturer (with a research degree in nutrition, biochemistry or chemistry, followed by specialization in nutrition or biochemistry) in Biochemistry and Nutrition at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, March 15).

Tutor (with a good honours degree in natural or physical sciences, and preferably with experience in extra-mural work) in Science—The Director of Extra-Mural Studies (University of Glasgow), 91 Oakfield Avenue, Glasgow, W.2 (March 15).

Chair of Nuclear Power, and Reader in Nuclear Power, at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 16).

Lecturer (with an honours degree in geography and special qualifications in physical and economic geography and geomorphology) in Geography in St. Salvator's College—Joint Clerk to the University Court, The University, St. Andrews (March 17).

Chair of Geology—The Registrar, University College, Singleton Park, Swansea (March 20).

Imperial Chemical Industries Research Fellows in Biochemistry, Chemistry, Chemotherapy, Engineering, Metallurgy, Pharmacology, Physics and subjects allied to chemistry or physics—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Demonstrators in Physics, and Demonstrators in Organic Chemistry—The Registrar, The University, Nottingham.

Deputy Director (with a good scientific background and able to formulate research projects which meet from time to time the needs of the industry, and also able to lead a research group successfully)—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22.

Lecturer (with high academic qualifications and some experience in the practical applications of electronics) in Electronic Engineering, with particular reference to electronics for purposes other than communications—The Registrar, The University, Bristol.

Master to teach Mathematics up to advanced level standard—The Director of Studies, Nautical College, Pangbourne, Berkshire.

Microbiologist (with a first- or second-class honours degree or equivalent qualification, and preferably with research experience), to assist in the study of fungi, moulds, etc., in their research aspects and in respect to their part in producing deterioration of materials, especially woods and textiles, under a variety of tropical environments (Ref. G.34/6A/AA); and Chemists (with a first- or second-class honours degree or equivalent qualification, and preferably with research experience) for work on general chemical problems (with opportunities for research) associated with the scientific study of the behaviour of a wide variety of materials (plastics, rubber, metals, fibres, etc.) in tropical environments (Ref. F51/6A/AA), at the Tropical Testing Establishment, Port Harcourt, Nigeria—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No.

Physical Chemists or Physicists (with a first- or second-class honours degree or equivalent in chemistry or physics and an interest in the study of high-speed phenomena) at a Ministry of Supply Research and Development Establishment, Waltham Abbey, Essex, to study detonation and deflagration phenomena in explosive systems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.35/6A/AA.

Physicist or Engineer (with a first- or second-class honours degree or equivalent and preferably with experience of servo-mechanisms, analogue computers or applied electronics) at the Royal Aircraft Establishment, Farnborough, Hants, for work on instruments for flight control and navigation—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.13/6A/AA.

Physicist (with a first- or second-class honours degree or equivalent in physics, and preferably with experience in one or more of the following: transducers, electrical recording apparatus, permanent magnetism and pyrometry) at a Ministry of Supply Research and Development Establishment, Waltham Abbey, Essex, for experimental investigations including study of transient mechanical phenomena—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 29/6A/AA.

Physicists and Electrical Engineers, Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree in physics or electrical engineering), at the Ministry of Supply Fighting Vehicles Research and Development Establishment, near Chertsey, Surrey, to study problems of crossing rough and soft ground by tracked and wheeled vehicles and to develop electronic recording techniques for evaluation of soil stresses and associated automotive problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.489/5A/AA.

Physiologist (with a good honours degree in botany, and some postgraduate experience in plant physiology), at the Cotton Research Station, Namulonge, Uganda, to study the growth of the cotton plant with particular reference to the physiology of crop development and lint quality—The Secretary, Empire Cotton Growing Corporation, 12 Chantrey House, Eccleston Street, London, S.W.1.

Principal (under 45, with a university degree in forestry, mature experience and an aptitude for instructing in all spheres of forestry subjects) of the Forest Training School, Londiani, Kenya—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, Westminster, London, S.W.1, quoting BCD.61/7/06.

Research Assistant (Biochemist or Biologist) to work on problems of nutrition and fertility, involving chiefly experiments with laboratory animals—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8.

Research Physicists; Electrical, Electronic and Mechanical Engineers, with the European Organization for Nuclear Research, Geneva, to assist in the design and construction of high energy accelerating machines and to carry out nuclear research—The Ministry of Labour and National Service, Almack House, 26 King Street, London, S W.1, quoting A.12/SW.1/18/CERN.

Theoretical Nuclear Physicist (with a first-class honours degree in mathematics or physics, together with several years postgraduate research experience in nuclear physics), to carry out fundamental research in nuclear physics, particularly on the theory of nuclear structure—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. No. A.799/2.

New Books

Titanium

By A. D. McQUILLAN, Ph.D., and M. K. McQUILLAN, M.A. **Price 56s.**

The fourth volume in the *Metallurgy of the Rarer Metals Series.* This series of monographs will provide a readable work of reference on the background and the metallurgical, chemical and physical data of the metal concerned, and will contain all the published information on each metal at the time of going to press. Subsequent volumes will cover beryllium, molybdenum, platinum and the metals allied with it, and uranium. **Already published : Chromium, Zirconium, Manganese.**

Micro-Indentation Hardness Testing

By B. W. MOTT, M.A. **Price 42s.**

Designed as a survey of modern developments in low-load testing, complete with the fullest possible bibliography, this work will prove an invaluable help both to those engaged in the metallurgical field, and other research workers requiring an application of the technique to a study of non-metallic materials.

Chromium-Nickel Austenitic Steels

By F. H. KEATING, F.I.M. **Price 25s.**

This book is primarily intended to be of service to the user of the austenitic stainless steels and it is based on the wide experience of Imperial Chemical Industries, Ltd. It provides an account, in the simplest terms, of those producing and fabricating processes of which the well-equipped user should have some knowledge.

This handbook is essentially a work of reference for the practical man rather than a treatise for the specialist. Certain simplifications of theoretical matter have been attempted in the interests of readers who are not trained metallurgists ; nevertheless, the book will have some value as a reference for the metallurgist, and is particularly suitable for the beginner and the student.

LECTURES AND COURSES

SOMERSET EDUCATION COMMITTEE

MID-WEEK RESIDENTIAL COURSES

March 19th-23rd Transistors (Introductory) May 14th-18th Numerical Analysis June 25th-29th Transistors (Advanced). For students with graduate or higher national certificate qualifications. Inclusive fee for each course £7 7s. Final enrolment 14 days before each course begins.

Details from the Warden, Dillington House, College for Adult Education, Ilminster, Somerset.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order, 1952.

UNIVERSITY OF THE WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

Applications are invited for appointment to the Chair of Physical Chemistry in the University's Department of Chemistry and Chemical Engineering, this being the second Chair in the Department. The Professor of Physical Chemistry will be responsible to the Head of the Department, who is also Professor of Organic Chemistry, for the courses he is called upon to give in physical chemistry and related subjects. Duties are to be assumed on August 1, 1956, or as soon as possible thereafter. The substantive salary scale attached to the appointment will be £1,650 by £50 to £1,950 In addition a married man will receive cost of living allowance at such rate as may be authorized from time to time, the present rate being £234 per annum Membership of the Provident Fund is compulsory. Membership of the Staff Medical Aid Fund is compulsory in the case of an officer who is found eligible for such membership.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1. The closing date for the receipt of applications, in London and South Africa, is March 26, 1956.

UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF PHYSICS

Applications are invited for the following vacancies: (i) Two Assistant Professorships, Nuclear or Solid State Physics or Spectroscopy (ii) One Instructorship (iii) Two Post-doctorate Research Fellowships First inquiries should be accompanied by brief particulars regarding training and experience.

Full information regarding these vacancies may be obtained from G. M Shrum, Department of Physics, University of British Columbia, Vancouver, 8 B C., Canada.

H.M. OVERSEA CIVIL SERVICE

Applications are invited for the following post: Assistant Conservator of Forests, Sierra Leone. Candidates must possess a university degree in forestry. Appointment on probation to the permanent and pensionable establishment in the salary scale £560 to £1,280 a year plus an allowance of £182 to £282 a year Outfit allowance of £60 on first appointment. Free first-class passages for officer, wife and up to two children under the age of 10 years Government quarters when available at moderate rental Generous home leave. Taxation at local rates

Apply giving brief particulars to the Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W 1, quoting reference BCD 61/15/04.

UNIVERSITY OF LONDON KING'S College will require in April if possible and in any case not later than October 1956 a Lecturer in Physics. Salary: £700 by £50 to £1,000: £1,050 by £50 to £1,400 with family allowances and superannuation benefits with starting point according to qualifications and experience. Applicants should preferably have a higher degree. —They should write for conditions of appointment and application forms to the Registrar, King's College, Strand, W.C 2, whom completed applications must reach by March 9

ATOMIC WEAPONS RESEARCH ESTABLISHMENT

ALDERMASTON, BERKSHIRE

requires

ANALYTICAL CHEMISTS

in the following grades

(A) Ref A770/34 PRINCIPAL or SENIOR SCIENTIFIC OFFICER to lead a team engaged on analytical problems associated with research and development work on both organic and inorganic chemistry; to be responsible for laboratory organization and the training of junior staff. Applicants should hold a first- or second-class honours degree in chemistry and have completed at least three years' postgraduate work with experience in the solution of analytical problems and the use of modern techniques Experience in micro-analysis an advantage

SALARY to be assessed according to age, qualification and experience

PRINCIPAL SCIENTIFIC OFFICER
£1,270 to £1,680 per annum
SENIOR SCIENTIFIC OFFICER
£1,105 to £1,270 per annum

(B) Ref. 1014/34 SENIOR EXPERIMENTAL and EXPERIMENTAL OFFICERS for research and development work in an analytical laboratory. The minimum qualification is H S C. (science) or equivalent, but a pass degree in chemistry is desirable. Applicants should have several years' experience in a research or inspection laboratory and a sound knowledge of basic analytical methods Experience in explosives testing would be an asset Normally candidates under 26 years of age (35 for the senior post) will not be considered unless exceptionally well qualified.

SALARY:
SENIOR EXPERIMENTAL OFFICER
£1,155 to £1,350 per annum
EXPERIMENTAL OFFICER £808 to £988 per annum

Contributory superannuation scheme. Married officers now living outside the Establishment's transport area will be eligible for housing on one of the Authority's estates; alternatively, assistance towards legal expenses incurred in house purchase may be available. Until housed a lodging allowance may be payable.

Requests for application forms by POSTCARD to Senior Recruitment Officer at the above address, quoting appropriate reference number.

COUNTY BOROUGH OF WEST HAM EDUCATION COMMITTEE

WEST HAM COLLEGE OF TECHNOLOGY
ROMFORD ROAD, STRATFORD, E.15
PRINCIPAL: E. A. RUDGE, Ph.D., M Sc, A.M.I.Chem E.

Required: Senior Lecturer in Mathematics. Candidates should possess honours degree in subject. Research experience desirable Scope of work covers mathematics up to requirements of London internal science degree. Appointment conditional upon acceptance by University of London as "Recognized Teacher." Salary: Burnham Scale (London).

Application forms and particulars may be obtained from the above-named.

R. OPENSHAW,
Chief Education Officer

Education Department,
95 The Grove,
Stratford, E 15.

DEPARTMENT OF SCIENTIFIC AND INdustrial Research requires an Assistant Experimental Officer at the Food Investigation Low Temperature Research Station, Cambridge, to assist in studying the chemistry and microbiology of spoilage in poultry General Certificate of Education advanced level in chemistry or biology and one other science subject and an interest in biochemistry. Over 22, pass degree, higher national certificate or equivalent generally expected. Inclusive salary 45½ hour week (men) £315 (age 18) to £690, (women) £315 to £601 Equal pay scheme. Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting G.29/6A. Closing date February 25, 1956

COCONUT RESEARCH INSTITUTE (CEYLON)

POST OF DIRECTOR

The Coconut Research Board of Ceylon invites applications for appointment as Director of the Coconut Research Institute of Ceylon. 1. Salary: Local candidates, Rs 18,000 by Rs.800 to Rs.30,000 per annum; Overseas candidates, £2,000 by £100 to £3,500 per annum at current exchange rates. A dearness allowance of 15 per cent of basic salary, a rent-free two-storey house with heavy furniture is provided. A successfu applicant will be required to contribute to a provident fund at the rate of 15 per cent of his basic salary and an equivalent amount will be paid by the Board A higher salary would be accorded *ad personam* to a successful applicant with eminent qualifications. The appointmen will be in the first instance for a period of four years, inclusive of six months end of contrac leave. It is terminable with three months' notice on either side A first-class sea passage to Ceylon will be provided for an overseas candidate his wife and children under the age of 18 years Similarly, return passages will be provided to the country of domicile at the end of the period o service. Leave and travelling allowances in Ceylon will be in accordance with the regulations of the Institute. 2. Qualifications: The post calls for proved high scientific attainments, preferably in fields related to soils or crops combined with administrative experience either as head or deputy in the organization and running of a research institute or university department Experience o tropical conditions would be an advantage, but is not an essential qualification 3. Functions: The Director's primary responsibilities to the Coconu Research Board will be the administration of the Institute and the direction of the research activities of the Institute for the improvement of the yield and quality of the products of the palm. He will also be responsible to the board for the administration of replanting, rehabilitation and new planting schemes for the Island and for public relations General: The laboratories of the Institute are situated in the main coconut growing area of the Island, 32 miles north of Colombo. There is a scientific staff engaged in technological chemistry, soil chemistry, agronomy, plant breeding, and crop protection 4. Applications: Particulars should be furnished by applicants of their age marital status, academic qualifications, and research and administrative experience. They should also provide a list of publications, copie of testimonials, and the names and addresses o the referees to whom confidential inquiries can be addressed. A medical certificate and a recen photograph should also be annexed to the application.

Further particulars, if required, may be obtained from the undersigned. Applications should reach the Chairman, Coconut Research Board, Department of Agriculture, Peradeniya, Ceylon, on o before March 31, 1956

Chairman
Coconut Research Board of Ceylon

UNIVERSITY OF DURHAM

KING'S COLLEGE, NEWCASTLE UPON TYNE

A graduate Technical Assistant is required to assist in biochemical research into certain aspect of diabetes The post would be suitable for a graduate of pass degree or equivalent standard in chemistry, biochemistry or physiology. I might be possible for a suitable candidate to stud for a higher degree Experience in steroid hormone analysis, while not essential, would be an advantage

Applications, with the names of two referees should be addressed to the Professor of Physiology, The Medical School, King's College Newcastle upon Tyne 1.

G R HANSON,
Registrar of King's College

SCUNTHORPE HOSPITAL MANAGEMENT COMMITTEE

LINCOLNSHIRE RADIOTHERAPY CENTRE
(50 beds)
MEDICAL PHYSICIST

Immediate vacancy in expanding department including developments connected with rotation therapy and radioactive isotopes. Previous experience desirable but not essential. Probationar period of two years for new entrants to Healt Service. Salary scale (first- or second-clas honours) £525 by £25 to £625—others £475 by £25 to £575 Scale after probationary period £65 by £30 (3) by £35 (3) to £845. Postgraduate experience considered in fixing entry point Superannuation scheme.

Applications, naming two referees, to Grou Secretary, War Memorial Hospital, Scunthorpe beetles which prey on various immobile scales on citrus. In the Sudan Gezira, numbers of cotton whitefly are reduced by the activities of several species of parasites and predators. The latter are mobile whereas the immature stages of their host on which they feed are immobile. It is possible that numbers of whitefly in unsprayed fields adjacent to sprayed ones may be increased by the loss of parasites and predators moving into sprayed fields. This aspect of interplot effect has also received attention because, if shown to be real, it would result in a general lowering of level of yields on sprayed and unsprayed fields alike, and give rise to differences in yields between sprayed and unsprayed fields which are spurious even were such differences statistically significant.

These, and other aspects of interplot effect, are being investigated by workers in this department, and it is hoped shortly to publish more extensive results on this important aspect of the biology of pests of cotton. I thank the Chief of the Research Division, Sudan Government, for permission to publish this preliminary communication.

A Combinatorial Design for Experiments with Alternative Responses

Often an easily recognizable symptom of disorder, for example, chlorosis, appears in plants. If the reason is not obvious and a nutritional origin is suspected, nutrient elements are applied in one way or another to find which is deficient, results being judged on the qualitative response of a 'yes' or 'no' type. Usually, every suspected element is applied in a separate treatment, say, as an injection (if trees are concerned) or a spray. At least as many solutions (or more generally, kinds of treatment) are then needed as there are elements to try. The same is obviously true if each treatment supplies all but one of the elements considered. The number of treatments, the many solutions, and the cleaning of injection or spray apparatus with the care necessary in trace-element work, make the operations tedious and cumbersome. If the area under study is remote and inaccessible, difficulties become serious.

There exists, however, at least in the exploratory stage of inquiry, a theoretical possibility of obtaining the same amount of information from a number of treatments substantially smaller than the number of elements used. To demonstrate the principle with the simplest possible example, let us take two solutions: solution I contains iron and zinc; solution II, iron and magnesium. If only solution I brings about improvement, we conclude that zinc is deficient; if only solution II works, it is magnesium; if both I and II work, it is iron. Here with only two solutions we obtain information about three elements. Of course, the gain is small in this case.

Quite generally, an element can be distributed among n different solutions (treatments) in 2^n different ways. This number includes a 'distribution' consisting of absence from all n solutions. Actually, then, only $2^n - 1$ elements can be arranged between n solutions in such a way that each element will be present in a different combination of solutions. The combination of solutions that bring about the disappearance of the abnormal symptom defines the element responsible, because elements and combinations are in a biunique correspondence.

It follows that in an experiment with three solutions, seven elements can be used. One element will be present in all three solutions; of three elements, each will be in one of the three possible pairs of solutions: I and II, I and III, II and III; and three elements will each be in one only of the three solutions: I, II or III. Metals must be used as salts, so the element forming the common anion, for example, sulphur, will usually occupy the combination of all solutions. Similarly, four solutions provide for fifteen elements, which is about the maximum needed in the present state of our knowledge about plant nutrition.

Controls or plants not treated with any of the elements will, as a rule, be an essential part of the experimental scheme. Thus, strictly speaking, with $n + 1$ variants of treatment, we obtain information about $2^n - 1$ elements.

For conclusions from an experiment of this kind to be valid, the following conditions seem especially important: (*a*) the deficiency is simple: the deficiency of only one element is the cause of the visible abnormal symptom; (*b*) the remedy is unique: only the application of the deficient element improves the condition, no other element does; (*c*) there are no interactions: each element acts in the same way whether any other element is present in the treatment or not.

In practice, condition (*a*) will be satisfied in most cases, condition (*b*) nearly so. Condition (*c*), on which knowledge is scarcest, arouses most doubt.

In spite of these limitations, the idea seems to merit submission for discussion and trial by students of this branch of plant physiology and, indeed, by all those who work with experimental arrangements where the conditions of alternative response ('yes' or 'no'), simplicity, uniqueness and independence (*c*) can be assumed to prevail.

Relationship between Photosynthesis and a Homogeneous Protein Component of Plant Cytoplasm

Ultracentrifuged analyses by Wildman and co-workers[1,2] of cytoplasmic protein of leaf cells of a number of higher plants, extracted by mechanical disruption of cells into buffer, have revealed two major fractions: the first a homogeneous component of sedimentation constant (S_{20}) 16–18 Svedberg units (fraction I) and the second a polydisperse component with mean S_{20} of 3–4 units (fraction II).

These observations have recently been extended to a number of pasture plants[3], and the presence of similar components confirmed in the leaves of monocotyledons as well as dicotyledons. Fraction II displays a number of enzymic activities[4], whereas the biochemical function of fraction I has not been elucidated.

To determine further the distribution of these two components, a brief series of experiments was carried out. The soluble proteins derived from tissues of seedlings of monocotyledons were analysed in the ultracentrifuge. In the first group, seeds of wheat and Italian rye-grass were germinated and suspended over trays of nutrient solution, where they grew in normal daylight until the first leaf was fully formed. The proteins were extracted from both leaves and roots, as well as from the leaves of albino mutants which are produced by about 1 per cent of the seed. The albino character is believed to be controlled by a single recessive gene.

In the second group, wheat seedlings were grown in the dark on moist cloth until the etiolated leaf was just emerging from the elongated coleoptile. A number of shoots were dissected into leaf and coleoptile tissue, and the remainder exposed to 4,000 ft.-candles at 60° F., further shoots being removed and dissected after various periods.

In the third group, the growth of etiolated wheat seedlings was prolonged by supplying adequate mineral nutrients and sucrose as energy source until the leaf, still in etiolated form, had completely emerged from the coleoptile and could be readily harvested. In a similar fashion the growth of seedlings, in which the first leaf had completely emerged in light, was prolonged in the dark for a further ten days, and the first leaves harvested.

The amount of fraction I calculated per 100 parts of fraction II in the extracts from these various tissues is summarized in Table 1. This method of presentation is adopted because of the difficulty of finding a suitable criterion for tissues of such widely different type and composition. The results suggest that fraction I is found only in photosynthesizing tissue or in tissue which is capable of photosynthesis after it is exposed to light. In the experiments with etiolated plants, the rapidity of leaf development after exposure to light partly obscures the formation of fraction I in existing tissue; but the low level in relatively mature etiolated leaves, and the disappearance from normal leaf on transfer to the dark indicate that the fraction reaches full development only when active photosynthesis is taking place.

Table 1

Tissue	Conditions of growth	Amount of fraction I per 100 parts fraction II
1. Wheat leaf	Full light, 7 days	66
2. Wheat root	,, ,, ,, ,,	Nil
3. Rye-grass leaf	,, ,, ,, ,,	61
4. Rye-grass root	,, ,, ,, ,,	Nil
5. Albino rye-grass leaf	,, ,, ,, ,,	Nil
6. Wheat seedling leaf	Dark, 5 days	18
7. ,, ,, ,,	,, ,, ,, + 5 hours light	23
8. ,, ,, ,,	,, ,, ,, + 12 ,, ,,	29
9. ,, ,, ,,	,, ,, ,, + 20 ,, ,,	52
10. Wheat seedling coleoptile	,, ,, ,, + 20 ,, ,,	Nil
11. Wheat seedling leaf	Dark, 10 days	32
12. ,, ,, ,,	Full light, 7 days; dark, 10 days*	16

* During growth in dark, second leaf developed in etiolated form, but only first leaf, which had matured during growth in light, was analysed.

This association of fraction I with photosynthesis may prove to be merely coincidental; but as the part it plays in cell metabolism is not yet known, its connexion with photosynthesis is worth further study.

A Simple Method of assessing the Moisture exuded through the Skin of Cattle

To assess the moisture, use is made of the Assman psychrometer with the addition of a simple and easily made adaptation, which consists of a square polished metal box 4 in. × 4 in. × 2½ in., open at one end. Two holes, sufficiently large to hold the box against the air tubes by means of the threaded ends of the psychrometer cups, are punched in the closed end of the box, equidistant from the sides. In the middle of the bottom edge of each side a ½-in. square cut is made, and when the box is fitted over the psychrometer cups, the instrument is ready for use on livestock.

It is recommended that the wick of the wet-bulb thermometer of the psychrometer be examined frequently during a period of experiment to guard against its becoming dry. The wick should be discarded after thirty animal readings as dust particles from the skin of the animals are likely to cling to the moist surface, thereby impairing the efficiency of the instrument.

Air humidity is measured at a distance of 3 ft. from each animal and level with its back. The skin humidity is then taken from a site on the left side of the animal, over the last rib and as close to the vertebral column as possible, ensuring that the box is flat against the skin. The hair on the site chosen is clipped close to the skin, and the readings are taken at exactly 90 sec., both for atmospheric and animal measurements. In an initial experiment (see Table 1),

Table 1

Animal	Mile	Atmospheric dew point	Animal dew point	Ratio of animal dew point to atmospheric dew point	Skin temperature	Atmospheric temperature
261	0	57	60	1·05	86·4	65·3
296	0	57	58	1·02	87·6	66·0
300	0	57	57	1·00	83·5	67·1
261	1	59	60	1·02	86·2	85·8
296	1	57	59	1·04	90·9	86·9
300	1	58	58	1·00	85·8	79·7
261	2	56	58	1·04	93·0	83·3
296	2	57	61	1·07	92·3	81·5
300	2	57	58	1·02	94·5	86·9
261	4	54	55	1·02	96·1	87·8
296	4	54	57	1·06	94·8	79·7
300	4	53	61	1·15	97·3	88·7
261	7	50	58	1·16	99·3	82·4
296	7	50	58	1·16	98·8	88·7
300	7	52	57	1·10	100·6	89·6

skin temperatures on the same site were taken using a thermistor thermometer (kindly supplied by Dr. Findlay of the Hannah Dairy Research Institute, Kirkhill, Scotland). Unshaded atmospheric temperatures were also recorded at each time of measurement.

All wet- and dry-bulb readings were expressed as 'dew point', and it is suggested that a convenient method of expressing the difference between atmospheric humidity and the humidity of the air passing close to the skin of the animal would be the ratio of the animal dew point to the atmospheric dew point. Figures calculated on this basis are included in Table 1, which shows the results of readings taken on three mature Tanganyika zebu bulls which were walked a measured distance around an open paddock. Readings were taken before walking commenced and at 1 mile, 2 miles, 4 miles and 7 miles. Walking commenced at 08.00 hr., and approximately four minutes elapsed between measurements relating to each animal at the various distances.

The animals were not allowed to graze until after the seventh mile. The results in Table 1 show that the instrument is capable of demonstrating minor fluctuations in moisture exuded from the skin of cattle under relatively dry conditions, and the high readings obtained after the seventh mile suggest that prolonged exercise causes 'sweating' in the Tanganyika zebu.

The work is continuing, and a more complete report will be given elsewhere. I am grateful to the Director of Veterinary Services, Tanganyika Territory, for permission to publish this communication.

Thermionic Constants of Semi-Conductors

In some recent papers[1], we have described a convenient method of determining the thermionic constants of metals. The method consists essentially in determining, at different known temperatures, the rate of effusion of electrons through a small hole in a thin wall of a chamber made of the metal, instead of determining the direct emission from the surface. The advantage of the effusion method over the emission method is this. The expression for emission involves the transmission coefficient of the surface for electrons having the requisite momentum to cross the surface. This coefficient is very sensitive to adsorption of gases at the surface, and may differ considerably from unity. This coefficient, however, is eliminated in the expression for effusion, in the same manner in which the emissivity of the surface for electromagnetic radiations is eliminated when we take the electromagnetic radiations from a cavity through a small hole, instead of directly from the radiating surface. When the transmission coefficient is eliminated, any observed deviation of the A-coefficient in Richardson's equation from its theoretical value may be attributed to a small linear variation of the work function with temperature. Thus one is enabled by this method to determine not only the work function correctly, but also its temperature coefficient.

The thermionic constants of several metals have been determined by this method, using for this purpose a graphite chamber the walls of which were coated completely with the metal under study, by thermal or electrolytic deposition.

The main purpose of this communication is to direct attention to a new application of this method, namely, for the determination of the thermionic constants of semi-conductors, and to report some preliminary results obtained with nickel ribbons coated with the triple carbonates of barium, strontium and calcium in the molar percentages 47·5, 46·0 and 6·5 respectively. The ribbons were kindly supplied by Dr. D. A. Wright, of the Research Laboratories of the General Electric Co., Ltd., at Wembley. The ribbons were cut into pieces about 2 cm. in length, and a sheaf of them, held together at one end by a platinum foil, was fixed to the back of the graphite chamber, so that the ribbons did not come directly into contact with the graphite surface. The total surface area of these ribbons was more than twenty-five times the area of the effusion hole in our earlier measurements, and about fifty times in our later ones. The coated filaments were activated in the usual manner, and the effusion currents, corresponding to the saturation electronic vapour pressure of the oxide coat, in the temperature range 950°–1,160° K., were measured in the same manner as in our measurements on metals. (The electronic vapour pressure due to graphite, or platinum, is negligible at these temperatures.)

The currents corresponding to zero field were found to fit well with Richardson's equation, with $\varphi = 1{\cdot}55$ eV., and $A = 48$ amp. cm.$^{-2}$ deg.$^{-2}$. The latter value corresponds to a temperature coefficient of the work function $d\varphi/dT = 8 \times 10^{-5}$ eV. per deg., which is of the same order as in many metals. At 1,000° K. the current corresponding to effusion over the whole of the 2π-solid angle would be about 0·75 amp. per sq. cm. The corresponding current obtained by Elizabeth Grey[2] for maximum space-charge-limited pulsed emission directly from the surface of the oxide coat is 8 amp. per sq. cm., which is about eleven times as great. This ratio is of the order to be expected.

We thank Dr. Wright for supplying the coated ribbons, and for helpful discussions.

Use of Krypton-85 in measuring Gas Clean-up Rates

The intensity of gas discharges in switching devices for radar duplexers is such that clean-up of the rare-gas filling is an important factor, and may determine the life of such valves. Radioactive krypton, Kr-85 [1], has been used for measuring the rate of rare-gas clean-up in pre-T.R. valves, with promising results. Krypton-85 has a half-life of ten years and emits mainly beta radiation (680 keV.) and some gamma radiation (500 keV.). Thus it is a most convenient isotope to use, the radiation being readily detected by Geiger-counter or photographic techniques.

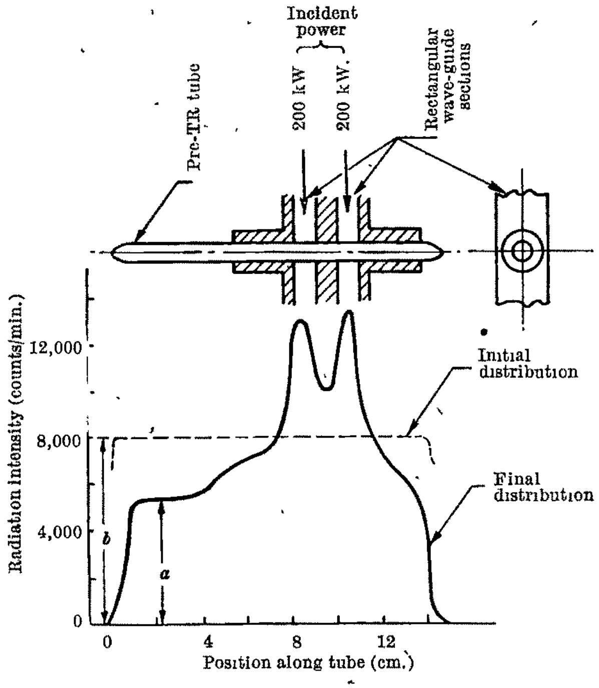

Fig. 1

Measurements using radioactive krypton can give information regarding the clean-up rate of this particular gas under certain conditions, and also enable a comparison to be made of the ability of different discharge conditions to clean-up rare gases.

Two techniques have been used to monitor the clean-up rate in pre-T.R. valves having walls of silica 0·020 in. thick: (*a*) The collimated beta radiation from a section of the valve remote from the discharge and gas clean-up region is monitored during the life of the valve, by Geiger counter. The activity then measured is due to free gas in the valve only, and hence the count-rate is proportional to the free gas density. (*b*) For low clean-up rates, a break-open test is most convenient. After a known period of life, the total activity of the valve is measured before and after breaking it open to the atmosphere. The residual activity of the valve after the free gas has escaped then corresponds to the quantity of gas cleaned-up into the walls of the valve.

A typical example of technique (*a*) is shown in Fig. 1. A silica tube pre-T.R. crosses two wave-guides, with 200 kW. of 3 cm. microwave power incident on each section of the tube. The tube contained 7 mm. mercury pressure of krypton. The lower diagram shows the distribution of the radiation emitted in a radial direction as a function of position along the tube-length, before and after a period of 250 hr. on life test. The ratio of final to initial gas pressure is given by a/b, and the area over which clean-up occurs is also indicated.

Radioactive argon and xenon are also available, but their usefulness is restricted by the low penetration from argon-37 and the short half-life (5 days) from xenon-133.

It would appear that the above techniques might be available in any experiments where clean-up of rare gases is being investigated.

The radioactive rare gases can be obtained from the Atomic Energy Research Establishment (Isotope Division), Harwell, whose helpful co-operation is acknowledged. We wish to thank the Admiralty for permission to publish this communication.

[1] Radioisotope Conference, vol 2 (1954)

Changes in Lattice Constant of Cr_2O_3 near the Curie Temperature

In 1951, a communication by me under this title was published in *Nature*[1]. It showed that as Cr_2O_3 was cooled through the antiferromagnetic transition region, the *c*-axis (hexagonal setting) contracted sharply, whereas the *a* axes decreased almost linearly. Recently, R. J. Davis and W. E. Armstrong (private communication), in a study of a system involving Cr_2O_3, found that the lattice parameters at room temperature of their Cr_2O_3 sample did not agree with those given by me. They also suggested that the cause of the disagreement was my indexing the $42\bar{2}$, 664 rhombohedral reflexion pair as the $42\bar{2}$, 652 pair. Re-examination of the data and a few additional measurements have shown that this is indeed the case.

Davis and Armstrong's values at 23° C. are plotted on Fig. 1 for comparison with the values obtained by re-indexing my results. It is apparent that a slight discrepancy in the *c*-values still exists. Fig. 1 also shows that the *c*-axis lengthens rather than contracts as the material is cooled through the antiferromagnetic transition region, whereas the *a*-axes decrease in a non-linear fashion in the same temperature-range.

The c/a ratio for Cr_2O_3 is observed to increase as the temperature is lowered through the transition. The rhombohedral angle α decreases sharply in the transition region, and the rhombohedral *a*-axes decrease linearly within the experimental error.

New observations have been made at room temperature and at approximately 95° K. with a 'Norelco' high-angle goniometer diffractometer. In the front reflexion region, there is no ambiguity in indexing, and the changes in position of the 110 and

PHOTOGRAPHY AT WORK

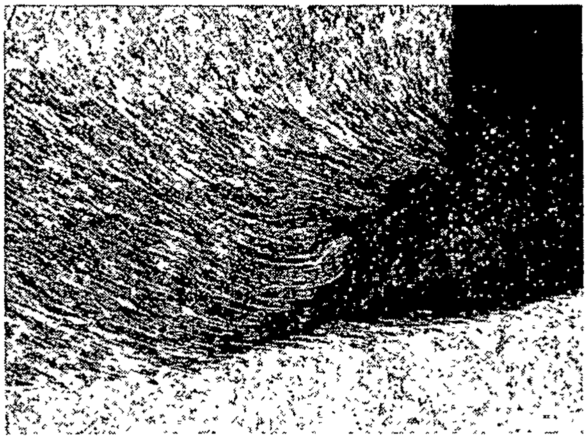
—proving that standard practice is not always best practice

Standard practice in the production of blanked metal parts was to use a die with a sharp edge.

But the Production Engineering Research Association were not satisfied that this was the *best* practice. So they put photography to work — to get the facts.

Using the 'Kodak' 0.250 Plate*, PERA carried out controlled research. They made photomicrographs of the results of tests on various pieces of metal — and these photomicrographs proved that metal parts blanked with a round-edged die, with appropriate clearance between punch and die, were of better quality than those made with a sharp-edged die.

** Sensitivity of the 'Kodak' 0.250 Rapid Orthochromatic Metallographic Plate is highest in the region of maximum visual sensitivity, where most microscopes yield sharpest focus. This is only one of the reasons why it is preferred by research workers. Let us send you Kodak Data Sheet PL-11, which gives full details.*



Photomicrograph showing deformation of metal when blanked with a sharp-edged die.

The VIBRON

A British achievement!

The Vibron Electrometer is a new instrument for measuring, with exceptional stability, very small currents from a high impedance source.

The 'heart' of the instrument is the E.I.L. VIBRON vibrating condenser unit, a precise electro-mechanical device which performs some 50 times better than the conventional electrometer valve.

The Vibron Electrometer is being used for ionisation current measurements, as an ultra stable pH meter and as a very high resistance megohmmeter.

Manufactured under British Patent No 550610 and Patent Application No. 35637/54

LEADERSHIP IN A MODERN DEMOCRACY

IN his autobiographical volume "Power and Influence", Lord Beveridge says he used to impress on his students at the London School of Economics and Political Science that science and practical reform call ultimately for different qualities and cannot always be served together; and he does not think that the exploration of new fields of thought and administrative work go well together. He commented that the Civil Service can be impartial, but Members of Parliament can be neither impartial nor scientific.

One may indeed challenge Lord Beveridge's view that those who spend their whole lives in scientific work tend to become unpractical or indecisive, whereas those who devote their whole energies to advocating particular measures of practical reform tend to become unscientific; at the same time we can maintain with Smuts (in his Sidgwick Memorial Lecture on "Democracy") that we need to find more effective means of making use of impartial expert opinion, so that decisions are taken with regard to the facts of the situation rather than to prejudice or passion. It remains true, however, that the statesman and politician must have regard to what is politically practicable as well as to what is technically feasible. Expediency is a principle which no one with claims to statesmanship can ignore, whether or not we concede that expediency, and expediency alone, is the basis of all government as the first Earl of Lytton maintained.

For that reason alone the relations between theory and practice in politics are infinitely more complex than Mr. W. Esslinger has suggested in his recent book[*]. That the university can make an important contribution to the study of politics is not in dispute. It has been urged, for example, by such authorities as Sir Ernest Barker and by his successor in the chair of political science at Cambridge, Prof. D. W. Brogan, as well as by Prof. K. C. Wheare at Oxford. Prof. Brogan sees the study of politics as the study of the means whereby liberty and authority may be best combined, and the dignity of the free man is made compatible with the highest and richest forms of co-operation. Nevertheless, he doubts whether politics can be, in any but the most special sense, a science; and it may be suspected that neither he nor Prof. Wheare would dissent from Lord Beveridge's view as to the impracticability of combining the service of social and political science and the practice of the arts of democratic government in one person.

What Prof. Brogan claimed in his inaugural lecture was that by its study of politics the university could, as Sir Ernest Barker urged in another connexion, "enlist the effective thought of the whole community in the operation of discussion". The ten years since this lecture was delivered have increased our need for strengthening the power of discussion, for broadening civic intelligence and for extending civic knowledge; nor are we using the new means and opportunities of doing so even to the extent necessary to counterbalance the decay of former means of public discussion. We are indeed increasingly better equipped to understand society and mankind, and better able to study society and man and the institutions, traditions and historical conditions that limit and constrain purely political activity than any earlier age; and Prof. Brogan frankly claimed then that the teacher and student of politics in the university has the duty in his teaching and writing of imparting in this double activity as much as possible of the standards of university teaching and research. When, moreover, he continued that the university contribution to politics must often take the form of developing new and deeper understanding of old truths, he came very close to the thesis which Mr. Esslinger expounds.

Arguing for the necessity and possibility of a practical science of politics, Mr. Esslinger suggests that our predicament to-day arises primarily from our lack of rapid adaptation to the swift advances of science and technology and to the loss of our belief in the certainty of progress: we need, he suggests, a practical science of politics from which a political technology can be derived; but the difference between the two is never explained. Though he recognizes that education must cultivate the scientific spirit and that what matters is the scientific attitude, his argument is not made clearer when he gives fresh currency to the term 'sciencing' which L. A. White coined before the War. The term is never defined, nor does Mr. Esslinger ever appear to attach any meaning to it that would justify such a monstrosity.

Mr. Esslinger contributes, in fact, very little to the discussion as to how best we can improve the prospects of obtaining political actions determined more by the facts of the situation than by the prejudices of particular parties or groups, or by traditions which are no longer relevant. Nevertheless, when his counsel is not clouded by jargon, his views do not appear to be widely different from those of Barker, of Wheare or of Brogan, for example. The task of the scientist, as he sees it, is to reconsider the old points of difference and by creative and imaginative thinking indicate new solutions. He admits that there can never be the same accuracy as in the physical sciences; we cannot artificially create and reproduce the conditions of a social or economic process, nor can we even be sure that what works in a small community will work also in the whole State. A knowledge of interrelations and facts provides, none the less, the basis of good judgment, and the power of judgment can be trained in politics as in other fields.

Mr. Esslinger's plea, in fact, seems to amount in essence to one that the universities should broaden the field of studies devoted to practical problems, and in discussing schools of politics he seems to be advocating essentially what Prof. Brogan did in his inaugural lecture at Cambridge; it is to the spread of the scientific outlook and the scientific approach to the problems of government that he looks for the preservation of mankind in this age of nuclear power. The inherent difficulties in any approach to world government lie outside the scope of his book, though his final chapter is an analysis of the reasons for the failure of the League of Nations; he insists that the continuance of civilization depends on our concentrating on and finding solutions for the great political problems of peace, employment, the improvement of the standard of living in backward countries and the rejuvenation of democracy.

---

[*] Politics and Science. By William Esslinger. Pp. xi+167. (New York: Philosophical Library, 1955,) 3 dollars.

It is in this connexion that he has a penetrating chapter on publication facilities, in which he emphasizes the importance of public discussion in testing the validity of new ideas and that this is even more important in respect of constructive thinking than of fact finding. This plea for better facilities for the publication and discussion of ideas is not to be dismissed lightly. It finds some support in the discussion on research in the social sciences arranged by the Parliamentary and Scientific Committee on December 13, 1955, and in passages in the paper, "The Intellectual Individual in Contemporary Society", which Mr. N. G. Fisher, formerly chief education officer for Manchester, read before the Manchester Literary and Philosophical Society last April and which has now been published in the Society's *Memoirs*.

Mr. Fisher, while agreeing that systematic training in orderly methods of thought is indispensable for administration, points out that the practical man must learn the limits of order and system when applied to human affairs, and that illusions accumulate around the intellectual approach to administration. Society works by processes largely spontaneous, seldom predictable and always untidy, and there is a law of compensation in human affairs which determines that nothing is ever as radically good or bad as it is intended and ought to be. On the whole, intellectuals make bad politicians, and politicians make bad intellectuals.

Mr. Fisher would have intellectuals critical of their society; but his lecture offers cold comfort to those who look for the spread of reason or science into public administration and world government. Nor is optimism encouraged by the passage by Keynes on his contemporaries in "Two Memoirs" which he quotes: "We were not aware that civilization was a thin and precarious crust created by the personality and will of a very few and only maintained by rules and conventions skilfully put across and guilefully preserved. We had no respect for the traditional wisdom or the restraints of custom. . . . It did not occur to us to respect the extraordinary achievements of our predecessors in the ordering of life (as it now seems to me to have been) or the elaborate framework which they had devised to protect this order".

Mr. Fisher is no more encouraging as to the value of improved means of communication, though here he is somewhat contradictory. Criticism he admits as a form of leadership, if free of personal animus and divorced from emotional compensations. Clearly he distrusts the intellectual generally in this respect, for he refers in conclusion to the danger that the masses may take the intellectual too seriously.

Where then shall we look for leadership, and how can we hope for public policy to pay the regard to technical advance that is essential if mankind is to continue? There is more hope to be found in the approach indicated by those who took part in a discussion before the Parliamentary and Scientific Committee. Prof. James Drever, who introduced the discussion, was confident that the various social sciences can contribute to the solution of problems set by race relations and international tensions, as well as by school and family and industry. Prof. R. W. Russell maintained that information about the behaviour of man as an individual and as a member of a social group is to-day put to more uses than ever before. Developments in psychological knowledge and technique have enabled the psychologist, with other biological and social scientists, to contribute increasingly, both as scientist and technologist, to the satisfaction of the growing demand for such information. As a scientist the psychologist is concerned with developing a coherent body of knowledge, consisting of general principles underlying behaviour; as a technologist he is concerned with solving problems arising mainly in the public services and in industry.

Prof. Russell thought that solutions to problems of human relations will increasingly be achieved on the basis of knowledge rather than of chance. Prof. T. S. Simey, who spoke as a sociologist, was concerned solely with problems of organization, and emphasized the importance of research in this field being independent politically, free from ideological strings and entirely above suspicion. A university department has an inherent advantage accordingly in organizing such research, so that the integrity of the research worker is established. It is also essential that the objectives of the work should be generally accepted as practical and desirable, and that there should be freedom to make mistakes.

This discussion before the Parliamentary and Scientific Committee went some way to promote the public understanding which is essential if effective work is to be done in the political or social sciences. Such understanding is indispensable for adequate finance to be forthcoming and research maintained on an adequate scale over a term of years, and it can assist also the recruitment of the right type of staff on which Prof. Simey laid stress. Our best hope of advance and of the increasing penetration of the scientific outlook and method into public affairs lies in education—in scientists themselves making the fullest and most effective use of whatever opportunities discussions such as this may offer, or meetings of the British Association, or the Press or radio. It depends, too, on the way in which we tackle the problem of general education not merely of the scientist himself but also of the arts graduate, and at the technical college and in the schools as well as at the university. It is linked up with the problem of adult and further education in general. Spectacular advance is not to be expected; but the patient, determined and sustained pursuit of public education by all such means offers the surest hope of bringing the grave issues of public policy to-day to a level of public understanding in which they can be handled with reason rather than with passion and prejudice.

THE ROYAL DUBLIN SOCIETY

The Story of the Royal Dublin Society

By Terence de Vere White. Pp. vii+228+13 plates. (Tralee: The Kerryman Limited, 1955.) 21*s*.

THE eighteenth century in Ireland was a period of contrasts. While the existence of wealth and culture was evident in Dublin and the larger towns, poverty and ignorance were widespread. Such was the situation when a small band of enthusiasts met together in 1731 and founded "The Dublin Society for improving Husbandry, Manufactures and other Useful Arts and Sciences". As the author of this book, Mr. Terence de Vere White, points out, each of the founders of the Society was expected by the rules to make a study of some special subject and to report to the Society any relevant information he could obtain by reading, conversation or his own experiments.

The Society, later known as the Royal Dublin Society, has had a chequered history, and many of those who know only of the way it has developed during recent years will be grateful to Mr. White for the interesting account he has produced. The story he tells is largely that of the various men who have played a part in building up the Society during the past two hundred years. Such a treatment makes easy reading, but some of the more irrelevant biographical details might well have been replaced by a fuller account of the work which was done. Scientific activities, especially, receive less attention than they deserve. Throughout its career the Society has given direct support to scientific projects likely to be of benefit to the country, one of the most notable of which was the Radium Institute it established at the instigation of the late Prof. John Joly. In addition, it has helped in the advancement of science in Ireland by holding regular meetings which bring together scientific workers from the universities and other institutions, the papers read at these meetings being afterwards published by the Society. In earlier days it appears that this form of activity was thought to overlap that of the Royal Irish Academy, and an interesting account is given of the brief and indecisive struggle for supremacy which occurred between these two learned bodies some seventy years ago. Mention is also made of the controversy aroused by the proposal, strongly supported by the physicist, G. F. FitzGerald, that the Society should grant fellowships.

However, the promotion of scientific research is but a part of the activity of the Royal Dublin Society and is probably of little direct interest to the majority of its members. The increasing popularity of the Spring Show, and especially of the annual Horse Show, has brought unwonted prosperity. This has enabled the Society to improve its amenities and attract a record membership. It has also served to emphasize the advantages available to an organization which can pull up on the swings what it loses on the roundabouts. One is tempted to speculate what would have happened if men with large ideas had not come forward when they did to found the Dublin Society. The growing tendency to specialization would most likely have led to the founding of smaller bodies, and while some of these would have been successful, others might have wilted through lack of support. As it was, the widely extending roots of the Dublin Society enabled it to expand freely in various directions. Branches such as museums, a botanic garden, an art school and a veterinary college grew out and later became separated from the main stem. The remaining branches continued to give each other nourishment and support. Such an organization has needed a long time for its development, and the story Mr. White recounts was worth telling.

N. G. BALL

ADVANCES IN PROTEIN CHEMISTRY

Advances in Protein Chemistry

Edited by M. L. Anson, Kenneth Bailey and John T. Edsall. Vol. 9. Pp. viii+542. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1954.) 10.50 dollars.

THIS volume maintains the high standard of its predecessors, and like them is so varied as to contain something of interest to most students of proteins. The biochemists will enjoy the article by H. R. V. Arnstein on the metabolism of glycine. As the simplest amino-acid, it enters into many synthetic and degradative reactions, besides its role in protein synthesis, and Dr. Arnstein's article contains a wealth of information on all aspects. M. I. Chalmers and R. L. M. Synge discuss the digestion of proteins and nitrogenous compounds in ruminants—a not unimportant subject, as much of our protein reaches us from the plant via the rumen. The article recalls war-time attempts to utilize the synthetic powers of the ruminant by feeding urea; but the authors conclude that there has been little evolutionary pressure towards an economical use of protein under generous feeding conditions.

The article on the formation, composition and properties of the keratins, by W. H. Ward and H. P. Lundgren, will be of interest both to protein chemists, because their fibre-like nature and great stability make them excellent materials for physical studies, and to technologists, because of the great importance of the wool and leather industries. The basic knowledge of these materials is fully reviewed. S. I. Mizushima reviews the molecular structure of some dipeptides and synthetic polypeptides mainly from the point of view of structure and physical properties. M. Laskowski and M. Laskowski, jun., discuss trypsin inhibitors, and J. P. Greenstein the resolution of racemic α-amino-acids. The remaining articles are more physico-chemical in character. D. F. Waugh's discussion of protein–protein interactions is extremely wide, and includes much information on protein structure and on the changes which particular proteins undergo when treated with various reagents; it also discusses a number of specific types of interactions, for example, antigen–antibody and enzyme–substrate.

Finally, D. F. Cheeseman and J. T. Davies discuss physico-chemical and biological aspects of proteins at interfaces. On the whole, the study of proteins spread as films at interfaces has been disappointing since, as these authors point out, the specific properties are lost when unfolding takes place. The method on the whole has thrown little light on protein specificity or size, but the authors are able to deduce some interesting reactions of drugs and growth regulators.

J. A. V. BUTLER

THE ORIGINS OF EDUCATION

Ancient Education

By Prof. William A. Smith. Pp. xii+309. (New York: Philosophical Library, 1955.) 3.75 dollars.

PROF. WILLIAM A. SMITH might well have lost would-be readers by his turgid preface. "Since education is a broad concept," he says, "a concept the connotation of which ranges all the way from the total socialisation process operative in a society to formally organised institutional programs, its scope for historical treatment must of necessity be delimited." There are twelve abstracts in those lines. But his book is, in fact, altogether stimulating. The enormous field he has to cover, in surveying the great civilizations of the ancient world, makes for speed and directness and thereby saves him willy-nilly from overmuch technical jargon. Furthermore, his pages read all the more smoothly for being very systematic. One knows precisely where one is the whole time.

A book on ancient education was long overdue, for the treatment in the standard histories of education at large has rarely yet been more than merely tantalizing. Nor have all these standard histories been quite clear as to how far 'education' means the same when they are looking at Ancient Sumer as when they are on the main highroad with Plato's Academy or Medieval Scholasticism or the Charity Schools. Here Prof. Smith speaks from strength. By education he means something both wider and deeper than "the formal school tradition" of a civilization: deeper, because in fact more than half his study of each great age is devoted to its cultural pattern, rooted in its religion, writing-system and habitat; and wider, because his focus is as follows: "Formal education arose initially to supply *training for specialists*—scribes, priests, accountants. These functionaries arose with the *urban revolution*, and were indispensable in connection with the administration of the *economic surplus*" (p. 129; italics mine). This general thesis he sustains in his first chapter, on the "Grand Divisions of Cultural History", which is certainly a fascinating build-up from the Lower Palæolithic families by way of the "Neolithic revolution" into urban centres needing specialization of function and therefore formal education (the whole transition illustrated archæologically in Mesopotamia).

The great peoples then surveyed are those of Mesopotamia, Ancient Egypt, Ancient India, Ancient China, Greece, Rome and the Hebrews—with a concluding chapter on 'anthropologically primitive societies to-day as living witnesses of the 'nonliterate' stage. The pace is fast, and the narrative a deft outline. One is not sure whether the book is primarily for the reader knowing nothing of the matter until he comes to it, or the student needing revision and a refresher. Certainly both will find in it plenty of great value. At times there is masterly summarization; as, for example, that on Aristotle: "The forms as such do not change, but matter is constantly taking on new forms; hence the sensible world is perpetually changing, and as it does so new forms are realising their potentialities or purposes". But there is equally too much sheer repetition, and too much of "as *X* states", or (oftener) "stresses", or (most of all) "aptly puts it". These quirks are the more irritating since the author can be really profound and graceful when he takes the trouble: for example, in explaining how and why the educational contribution of the Greeks towers above that of contemporary teachers in India and China. "The Indians (Aryas), initially a jolly and extroverted people, early fell under the sway of a sacred literature and a tyrannical priesthood. The Chinese escaped the sacred and the priestly, but succumbed to the past. . . . By way of contrast, the Greeks had no sacred book, no priestly hierarchy, and no authoritarian tradition to keep them from speculating about the nature of man and the world. Their geniuses were, therefore, relatively free. . . ."

That is good writing; and in this book by the former professor of education in the University of California, which makes no claim to great originality and is based on a massive bibliography of already-published studies, there is much like it.

A. C. F. BEALES

DEVELOPMENTS IN TECHNICAL EDUCATION

Technical Education

Its Aims, Organisation and Future Development. By Dr. P. F. R. Venables, with five chapters by Specialist Authors. Pp. xii+645. (London: G. Bell and Sons, Ltd., 1955.) 42*s*. net.

"THOUGH technical education is but a small sector of the whole field of education, it nevertheless has a lasting significance in meeting the economic needs of the country through industry and commerce, and in the importance that work and education for work must always have in the individual lives of innumerable people." In these words, Dr. P. F. R. Venables in his preface succinctly states the case for a wider understanding, on the part of both the public and experts, of this field of education.

It is surprising that during the past twenty-five years only one other major volume has been published on the work of technical colleges; although innumerable reports, journals and conferences have dealt with special aspects of technical education. It is therefore most timely that this very comprehensive and authoritative work should appear in print in the same year as Parliament has sanctioned the creation of a diploma in technology and a national council to control the award of that degree-level qualification.

The whole volume comprises twenty chapters: introduction; the colleges; the courses; co-operative partnerships; liaison with industry; selection and placement; seven specialist chapters on selected industries or studies; higher technological education; finance and administration; students' problems; staffing; buildings; and prospect. There are also copious statistical appendixes, a subject index and a name index. Each chapter is very fully annotated by references to a bibliography, and there are many diagrams and graphs illustrating the text.

Any critical appreciation of the volume must depend upon the type of reader for whom the work is intended. It is doubtful whether anyone outside the boundaries of technical education, including the youth employment service and industrial training officers, would have either the understanding or the patience to comb through the mass of information and statistics presented to ascertain just how or why a technical education should be beneficial to his son or daughter. In that respect, the present work differs markedly from a similar volume on technical education recently published abroad in that it includes no photographic illustrations to stimulate imagination or to lighten the heavy going of text and tables.

For those who are directly concerned with technical education, however, this publication is invaluable: as a summary of the present state of technical education; as a mine of statistical information; and as a fairly stated point of view on present problems and on proposed future development. On this last-named point, however, it is noteworthy that although five specialist co-authors were called in, these and the main author are all without exception principals of colleges. The outlook of the class-teacher, the governor and councillor, the education officer, the regional council secretary, the youth employment officer, and of the industrial training executive are thus perforce excluded, or stated at second hand. At first sight, it may seem regrettable that the idea of "partnerships in technical education" so eloquently extolled in Chapter 5—"Running through all are three essentials, administrative, industrial and academic, and all must be preserved in balance if satisfactory harmonious progress is to be made"—could not have been given practical expression in the compilation of this most comprehensive work. No reader of this book, however, more especially Dr. Venables's colleagues in technical education, will fail to be impressed by the immense task of authorship undertaken by him; nor to be grateful that, for a very reasonable price, a handbook of present-day technical education can be placed upon one's desk for day-to-day reference—for the first time since the War.

This treatise can therefore be warmly recommended to teacher, administrator and industrial training officer alike. It should also, by the synthesis it alone provides, do a great deal to place technical education in the forefront of progress.

HUGH A. WARREN

EMULSION POLYMERIZATION

Emulsion Polymerization

By Frank A. Bovey, I. M. Kolthoff, A. I. Medalia and E. J. Meehan. (High Polymers: a Series of Monographs on the Chemistry, Physics and Technology of High Polymeric Substances—Vol. 9.) Pp. xii+445. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1955.) 12.50 dollars.

SINCE emulsion polymerization was first described some thirty years ago, it has attracted a great deal of attention, and it has been found that emulsion polymers may differ very significantly in properties from their counterparts made in other ways. Much of our present understanding of this process arose from the massive effort devoted in the United States during the Second World War to the development of a synthetic rubber industry. The authors of the book under review were intimately involved in the fundamental research programmes associated with that effort, and write from a broad background of knowledge of the polymer field.

The specific problems of emulsion polymerization cannot even be formulated without an understanding of the process of polymerization in simpler systems. The authors might well have assumed their readers to possess such knowledge, or left them to acquire it from other available sources. Instead, they have chosen to make the book essentially self-contained. Following an introductory chapter, the next three chapters outline a treatment of free-radical polymerization which for the most part is not restricted in its application to emulsions. Chapter 5 gives an account of the properties of soap solutions and their ability to solubilize organic liquids, and thus leads up to Chapter 6, which discusses in detail the kinetics of emulsion polymerization. Following a general chapter on inhibitors, the authors turn to copolymerization, and show how normal copolymerization may be modified when the reaction is carried out in emulsion. A chapter on experimental methods includes a brief review of molecular weight procedures, while the final two chapters give a rather full account of the various systems used for the production of the American synthetic rubber *GR—S*.

This is a most interesting and very well-written book, and will be widely welcomed for its connected account of the problems of emulsion polymerization. Because of the plan adopted, the title scarcely does the book justice: it could fairly be described as a general text-book of polymerization, with special reference to the problems of emulsion polymerization. The general sections of the book are of the same high standard as the more specific, and can be confidently recommended as an excellent introduction to the subject. The book is indeed one which might well be put into the hands of students were it not for its unfortunately high price.

G. GEE

ELECTRICAL SUPPLY SYSTEMS IN THE UNITED STATES

Electrical Transmission and Distribution

Edited by Bernhardt G. A. Skrotzki. (Electric Utility Library.) Pp. ix+448. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 56*s.* 6*d.*

MANY good books have been written on the subjects of the generation and mains transmission of electrical energy, but the equally important one of distribution is possibly less well covered. In this volume it is pleasing to find the subject dealt with fully and in considerable detail. Written in an informal style, the book deals exclusively with practice in the United States, but British engineers will find much to interest them therein on this account. The treatment is more descriptive and practical than purely theoretical, and is written for those on the supply side rather than from the point of view of the designer of equipment. An introductory chapter deals with elementary electrical theory so far as is needed for the subsequent treatment.

The major part of the work is devoted to distribution systems, starting with a chapter on mechanical aspects, including formulæ and calculations for poles and conductors, and concluding with some useful information on cables. Electrical characteristics are next treated, including voltage-drop calculations and descriptions of system arrangements and voltage-regulation methods and apparatus. In this connexion it is interesting to note the wide use made in the United States of single-phase three-wire supply, a system practically unknown in Britain. The use of capacitors for the improvement of the power factor is given most of a chapter to itself, while another one is devoted to protection, including examples of short-circuit calculations. Another chapter is devoted to load characteristics. Diversity and coincidence, problems of varying load, and planning for possible future load-expansion are all dealt with adequately.

Apart from the distribution aspect, there is a short section on transmission, in which overhead lines and cables are described with some useful figures and much practical information. Included also are accounts, mainly descriptive, of transmission switchgear and miscellaneous apparatus—rectifiers, frequency changers, etc.—together with a section on street lighting which makes interesting reading on account of the wide use of the series system in the United States.

The book can be recommended to those interested in the supply industry on the distribution side, and for general reading to university engineering and advanced technical students. G. H. PLATT

CINEMATOGRAPHY IN SCIENTIFIC RESEARCH

Research Films in Biology, Anthropology, Psychology and Medicine

By Anthony R. Michaelis. Pp. xvi+490. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 10 dollars.

CINEMATOGRAPHY has been, and is, used by scientists for a number of different purposes. First, a film may be used as a method of illustration in teaching; secondly, it may be used for recording and demonstrating methods and techniques used in research; and thirdly, cinematography can be used as a research method in its own right. Obviously, such a classification cannot be hard and fast, for a fact discovered by cinematography often finds its way into a teaching film; indeed, it would be strange if it did not. But it is primarily with the last of the three categories of film just mentioned that Dr. Michaelis treats.

In this most comprehensive book are reviewed the origin and development of cinematographic methods used in the study of the sciences listed in its title. In this wide field it is not surprising that the number of techniques is large and that the descriptions of them are widely scattered, both in journals devoted to scientific photography and in the journals of the various specialities. Dr. Michaelis, himself a scientific cinematographer of distinction, has set out to review this field and to provide those who are interested in the subject with an authoritative survey.

The large amount of information which Dr. Michaelis has gathered presents its own problems when it comes to be marshalled for the instruction of the reader. The author's method has been to give a general introduction dealing with definitions of cinematography and research films, with the early history of research films, and then to deal with those points which may be considered as general to all the sciences under review. These sciences are then considered in turn, being divided into biological, human and medical science. In each section Dr. Michaelis explains how cinematography can best be used in that subject and goes on to describe the relevant special methods and concludes with a review of the use to which the research film has been put. In some instances he makes suggestions as to further research by such methods.

This book, therefore, is of value not only as presenting a summary of the methods of cinematography in research, but also as a history of research films.

It is possible to suggest that perhaps these two aspects of history and method have not been sufficiently separated to enable the reader primarily interested in methods to refer to them without having to read a rather too large amount of history also. To this it might well be replied that the development of methods is a matter of history and also that, in order to judge whether any one method is likely to be useful, it is as well to know the kind of result that has already been obtained by its use. However, the reader who wishes to use this book mainly as a source of methods is well catered for with an adequate subject index and also an author and reference index which includes some 1,490 entries.

Dr. Michaelis is to be congratulated on having produced a book which is a significant contribution to the history of cinematography and which also can be confidently recommended for the library of any laboratory in which studies using cinematographic methods are likely to be undertaken. It is well produced, and the misprints which seem inevitable in first editions are few. G. E. H. FOXON

THE FUTURE OF MANKIND

Two Ears of Corn, Two Blades of Grass

By D. H. Killeffer. Pp. x+139+36 plates. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1955.) 30*s.* net.

ABOUT a hundred and fifty years ago Malthus saw, in his own village, that the limit to the increase in population was determined by the quantity of food available. He suggested that life would be easier if man could adjust his rate of increase to the amount of food available. But the industrial revolution, with improvements in agriculture and transport by land and sea, made it so much easier to obtain food that during the next hundred years the population of Britain increased fourfold and there seemed to be no limit to our food supply. The difficulties of obtaining food during world wars have, however, made us think again about this problem of population and food supply.

Sir Charles Darwin in "The Next Million Years" (1953) concluded that "In the very long run of a million years the general course of future history is, most of the time, likely to be what it has been for most of past time, a continual pressure of population on its means of subsistence—with a margin of the population unable to survive".

Mr. Killeffer's book contains an account of the scientific and technical developments of the chemical and associated industries in the United States during the past thirty years. He writes with a good inside knowledge of his subject, and every paragraph reflects the optimism which is behind the growth of industries in his country. He reviews the industries producing drugs, antibiotics, chemicals from petroleum, synthetic rubber, vitamins, chemicals for the protection of crops from insects, weeds and fungi, atomic energy and radioactive isotopes, plastics and metals.

Then he considers the problems of the future. He has no fear that the growth of population in the world will ever lead to famine because "American Technologies are going to other countries for nationals there to develop and utilize". He explains that we shall never be short of metals, sources of energy to work our factories, or food. First there will be great advances in agriculture by improving both the intensity and extent of cultivation and fertilization of our fields. But eventually we shall produce our protein foods in factories by growing yeasts and moulds. But we may have to grow our sugars and carbohydrates on farm land where we can utilize the energy of the sun. He considers that "We already know how to live well even when fields and farms shrink. Centuries before we will need them for that purpose, our industry is already operating processes that will free us from the necessity of farming fields for food. We can properly put our fears in a deep freezer".

Mr. Killeffer believes that the social and political effects will be that "Universal peace can be easily and surely realized by applying technology and science through human co-operation and collaboration to solve the basic human problems of nutrition, health and resources. We already know how to produce plenty of food and how to free people from the fear of hunger and from the load that sickness, disease and misery lay upon them. We can overcome these terrors if we apply throughout the world the techniques that we already know".

R. E. Slade

NEW METHODS IN ASTRONOMY

Radio Astronomy

By Dr. J. L. Pawsey and Dr. R. N. Bracewell. (International Monographs on Radio.) Pp. x+361+23 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 55*s*. net.

THE invention of methods of producing and detecting electromagnetic waves of long wave-length which could signal information invisibly over long distances with no material medium was a remarkable outcome of the classical electrodynamics of the nineteenth century. Although radio has since then continued to attract the attention of physicists, especially for the knowledge it gives of the Earth's upper atmosphere and ionosphere, pure research interest in radio became dwarfed by comparison with that in atomic physics. Much effort, however, was devoted by radio physicists and engineers to the perfection of radio communication in its various forms, including the associated techniques of radar.

The astronomer has always held a unique place in science. In the interpretation of his observations he incorporates new aspects of fundamental scientific knowledge ranging from nuclear physics to cosmology. He observes phenomena in conditions impossible to attain in the laboratory. His inferences and speculations arouse widespread interest since they concern man's place in the universe. That radio should now be making a far-reaching contribution to astronomy is an unexpected development of recent years.

The explanation lies in the advance of radio technology as well as in astrophysical phenomena at radio wave-lengths. With radio receivers of special design the temperatures of objects can be measured by the radiation emitted to an accuracy of the order of one degree. Thus the temperature of the Moon can be measured by its radio emission. Radio can also measure the temperatures of ionized atmospheres such as the solar corona and interstellar ionized hydrogen in the vicinity of hot stars. In addition, there are solar and cosmic radio sources of amazingly high intensity, the interpretation of which is a challenge to the astronomer and physicist. Another discovery of great importance is the line emission at 1,420 Mc./s. (21 cm) from neutral hydrogen, from which there is no visual emission. This spectral line enables not only the spatial distribution of hydrogen in the galaxy to be studied, but also the velocity by the Doppler displacement. A valuable aid in determining the structure of the galaxy is thus provided. Radar techniques have been extended to the study of reflexions from meteor trails and echoes from the Moon. In these various ways radio has become the new tool of astronomy and has the advantage of being able to 'see' through terrestrial clouds and interstellar dust.

Dr. J. L. Pawsey is the leader of an Australian research group, in the Commonwealth Scientific and Industrial Research Organization, which during the past ten years has played a leading part in the development of this new branch of astronomy. In their new book, Dr. Pawsey and Dr. R. N. Bracewell have written a valuable survey and guide to the fundamentals of the subject. It is an excellent introduction for physicists wishing to learn both the radio principles and the astronomical background. Equally, it explains the radio methods to the astronomer, and astronomy to the radio physicist or engineer.

It is plainly not easy to plan a book covering such a wide field. The authors have approached their task by describing radio techniques and propagation through an ionized gas; then follows a chapter on visual solar phenomena and solar physics. It is not until p. 144, with the chapter on solar radio waves, that the detailed account of the radio astronomical observations begins. An initial perusal of the chapters on solar and cosmic radio waves may be advisable in order to appreciate more thoroughly the significance of parts of the previous chapters.

The whole book is clearly written and well illustrated. The authors have endeavoured to be impartial in choosing material from the now vast number of papers on radio astronomy. It is, of course, natural that any author should be most advantageously placed in describing the work of his own laboratory. The rate of progress in radio astronomy is so great that a book on the subject can never be completely up to date when it is published. Although inevitably there are omissions of some recent findings, this book by Dr. Pawsey and Dr. Bracewell admirably covers the basic work and fundamentals. J. S. Hey

The Boys' Country Book

Edited by John Moore. Pp. 352. (London: William Collins, Sons and Co., Ltd., 1955.) 15*s.* net.

Letters to a Young Naturalist

By Maxwell Knight. Pp. 192. (London: William Collins, Sons and Co., Ltd., 1955.) 10*s.* 6*d.* net.

THOSE who publish books for young people must find the task more difficult every day. First, because more books are being published than the reading public can buy. Secondly, because the books that are published are, on the whole, of good quality both in format and in content. It is not surprising, therefore, to find a well-known publishing company of children's books dipping into the past for ideas for new books which it hopes will be successful. The editor of the "Boys' Country Book" has turned to the "Boys' Own Book", published about 1860, and which contained much good advice about how to get the best out of riding, sailing, swimming, fishing, shooting and other activities beloved by boys; much country lore was intermingled with the advice. In his book John Moore has sought help from well-known writers like Spencer, Chapman, Jack Longland, Jacquetta Hawkes, Geoffrey Grigson, James Fisher, Eric Hosking and a score of others who write about country pursuits of diverse kinds. The majority have done their task well; a few have padded to fill out the pages and fortunately will be read and quickly forgotten by boys of good sense. Most of the book should arouse spontaneous interest with the majority of early teen-agers.

"Letters to a Young Naturalist" has been developed along the same lines as Gilbert White's "Natural History of Selborne". It may appeal more to young people than adults who, while recognizing the value of the natural lore it contains, would have preferred to have been spared some of the conversational exchanges between uncle, nephew and niece. Some children, too, might have preferred straightforward descriptions.

Careers for Graduates

A Handbook of Information. Edited for the University of London Appointments Board. Pp. vii+196. (London: The Athlone Press (University of London), 1955. Distributed by Constable and Co., Ltd.) 5*s.* net.

A VALUABLE service to graduates, headmasters and headmistresses, parents and scholars who hope to go to a university has been made available by the Appointments Board of the University of London. In 1924 the Board issued a handbook giving information about the avenues of employment open to graduates. This ran to three editions, the last being published so long ago as 1934. A fourth edition has now been prepared and is virtually a new book. So far as possible the employment of graduates and students in all faculties except theology has been considered, and the needs of both men and women have been taken into account.

The Handbook includes a select bibliography of current careers pamphlets, memoranda and books likely to be of interest to graduates, students and others; addresses likely to be required by those making inquiries and an index for convenience of reference. It is a model of succinct and lucid presentation, and should be a boon to many who have to choose careers for themselves; it will be even more useful to those who have to advise others about suitable means of training for careers. The weakness of the book is in its unconscious emphasis on 'professionalism'. It has long been known that Britain has not found enough enterprising young men to take the findings of scientific research and apply and develop them in industry. It is not enough to encourage graduates to seek careers in industry. They are most needed in production departments where qualities other than professional qualifications will be needed if they are to establish themselves and progress. It is difficult to see how, in a Handbook of this kind, the real challenge and opportunity which shop-floor industry presents could be presented. Perhaps that is a problem to which industry alone can find the answer.

T. H. HAWKINS

The Numbers of Man and Animals

Edited by J. B. Cragg and N. W. Pirie. Pp. viii+152. (Edinburgh and London: Oliver and Boyd, Ltd., 1955. Published for The Institute of Biology.) 15*s.* net.

IN September 1954 the Institute of Biology arranged a symposium in order to bring together specialists in many different subjects connected with the numbers of men and animals. Their deliberations were recorded and have now been put together in book form. The central theme of the conference was that, while the growth of human populations is strongly influenced by social and cultural factors which are much less important in other species, *Homo sapiens* is still an animal and many aspects of his relationship with his environment, with other species, and with other members of his own species, are open to biological analysis. The analysis extends into most aspects of biology and sheds light not only on the reproductive habits of man but also on those of his domestic animals, parasites and pests. It became clear from the symposium that a great deal of money will have to be spent, and the number of people engaged on biological investigations increased, if essential information on population control or stabilization is to be obtained.

The book contains a record of all the papers presented by speakers as well as an idealized version of the discussion. It has been ably edited on behalf of the Institute of Biology, and the Institute has increased its prestige by arranging such a desirable and useful symposium.

A Manual of Paper Chromatography and Paper Electrophoresis

By Richard J. Block, Emmett L. Durrum and Gunter Zweig, with the co-operation of Raymond LeStrange, Winston H. Wingerd and Kathryn W. Weiss. Pp. viii+484. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 8 dollars.

THIS book is written in two sections: the first, by R. J. Block and G. Zweig, is on paper chromatography; and the second, by E. L. Durrum, is on paper electrophoresis. The first section is a revised version of the well-known monograph, by Block, LeStrange and Zweig, published in 1952, and maintains the high standard of that work. All practical aspects of paper chromatography are treated with remarkable thoroughness and presented clearly with many helpful recommendations. This section is a complete practical guide for all who employ paper chromatography.

There is ample justification for a monograph on paper electrophoresis, since it is now well established, but it is questionable whether the best course was to have included it in one volume with another technique which occupies four-fifths of the space. Because of this restriction, the author has been unable to give the subject the thorough treatment that is such a notable feature of the first section. For example, little is mentioned about pathological sera, although the widest application of paper electrophoresis is in the clinical field, and, because of presentation, the beginner may have difficulty in finding guidance. However, Durrum has dealt adequately with the theoretical side and has been able, from his experience as a pioneer in this technique, to provide valuable information concerning many practical details. The whole volume is attractively produced and includes a very full bibliography.

R. Consden

The Archæology of Sussex

By E. Cecil Curwen. Second edition, revised. Pp. xx+330+32 plates. (London: Methuen and Co., Ltd., 1954.) 25*s.* net.

Dr. E. Cecil Curwen is a well-known pre-historian, and he therefore writes from first-hand knowledge. The second edition of his work on the archæology of Sussex has been entirely brought up to date and gives an excellent general picture of the remote past in that county. The book is not intended for the specialist, but rather for the instructed amateur interested in archæology who is studying the ancient story of one of the more interesting parts of Britain. Dr. Curwen first sets the stage and then proceeds to deal with Sussex during the Stone Ages, the Bronze and Iron Ages and the Roman period. All accounts of Saxon times in the county have been omitted.

The only criticism that can be made is of the deliberate omission of any kind of gazetteer of sites. Here I cannot agree with Dr. Curwen that such things are only useful to specialists. Anyone visiting the county and wishing to explore the countryside would have welcomed such a list of sites with their ages and references to any relevant literature concerning them. For the specialist, of course, such a gazetteer would have been invaluable. One rather fears that the publishers probably felt they could not face the extra expense involved. All the same, this second, revised edition is an excellent work and should be on the shelves of everyone interested in the remote past of that part of England. The illustrations are well chosen, both the line-blocks and the half-tones; and there are a welcome number of the latter.

Miles Burkitt

Transistors

Theory and Applications. By Abraham Coblenz and Harry L. Owens. Pp. xv+313. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 42*s.* 6*d.*

Three years ago the authors gave lectures on the transistor at laboratories of the United States Signal Corps, shortly afterwards converting them into eleven articles for the journal *Electronics*, and now into a book. They have thereby attempted the formidable task of describing semiconductor physics, the metallurgy of germanium and silicon, techniques for manufacturing transistors and the equivalent circuits and applications of transistors, in language suited, as they say, to the practical technician.

The background physics given in early chapters is, however, disjointed and not always helpful or accurate. The uncertainty principle, for example, might well have been omitted. Davisson and Germer did not, in confirming de Broglie, pass electrons through a nickel slab to obtain clear, circular diffraction patterns on a photographic plate. Mobility, lifetime of minority carriers and the Hall effect are surprisingly left until much later in the book. The chapters describing the electronics, elementary circuits, small-signal applications and cascading of transistors—the centre third of the book—are, on the other hand, very satisfactory and should be of wide use. A chapter on large-signal applications is too confined to early work.

Manufacture is interestingly described, but diffusion is said to be the mechanism responsible for the p-n junction formed by that extensively used process of alloying indium to n-type germanium. The fact is that, during the furnace operation, the indium dissolves some germanium, much of which, contaminated with indium, is precipitated during cooling on to the undisturbed germanium, at first continuing the monocrystalline structure; diffusion is unimportant. Very little information is given on the design of transistors. The presentation maintains the high standards of the publishers.

J. R. T.

An Introduction to the Theory of Numbers

By G. H. Hardy and E. M. Wright. Third edition. Pp. xvi + 419. (Oxford: Clarendon Press; London: Oxford University Press, 1954.) 42*s.* net.

This text, widely recognized as probably the best general introduction to number theory, now appears in a third edition; G. H. Hardy died shortly after the publication of the second edition of 1945, and the revisions have been made by Prof. E. M. Wright, utilizing recent work. For example, the 1945 statement that there is no easy proof of the irrationality of π has been replaced by a concise and elegant proof due to Niven. But the major change is the insertion of an 'elementary' proof of the Prime Number Theorem, that the number of primes less than x is asymptotically equivalent to $x/(\log x)$. This proof, obtained by Selberg and Erdös and here given with improvements due to Wright, is by no means easy, but is technically elementary since it makes no use of complex function theory, and its discovery was the mathematical sensation of 1949.

Organic Syntheses

An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Edited by William S. Johnson. Vol. 34, 1954. Pp. vi+121. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 28*s.* net.

Among the thirty-four preparative methods described in this volume are two for cycloheptanone, each starting from cyclohexanone: the first method, using nitromethane and Raney nickel, gives a yield of 40–42 per cent; the second, in which *p*-tolylsulphonylmethylnitrosamide is used as a source of diazomethane, gives 33–36 per cent. The great variety of organic compounds contained in this latest issue may be indicated by mentioning azelanitrile, cetylmalonic ester, dimethylfurazan, diphenylacetylene, hemimellitene, 3-methylthiophen, *o*-phthaldehyde and tetralin hydroperoxide. The editors invite chemists to submit accurate details for the preparation of other compounds which might find a place in future issues, either by reason of their general interest or because they illustrate useful synthetic methods.

John Read

REVERSIBLE, HOST-INDUCED, CHANGES IN A STRAIN OF TOBACCO MOSAIC VIRUS

By F. C. BAWDEN, F.R.S.

Rothamsted Experimental Station, Harpenden, Hertfordshire

THE concept of variability is, perhaps, even less novel with tobacco mosaic virus, of which scores of strains have been reported, than with most pathogens, and describing yet another strain seems to need justifying. My justification is, not only that it changes more extensively than any strain previously described and that the large changes are reversible, but also that propagation in different host plants or environments so alters it that its properties depend less on those of the virus present in an inoculum than on the identity of the plants inoculated and the condition in which they grow.

Many of the reported strains were derived from Johnson's[1] tobacco virus 1, which is reasonably taken as the standard form of tobacco mosaic virus. These, like most others found infecting solanaceous plants, have very similar physico-chemical properties and are closely related serologically. Small antigenic differences have been detected between some, but most have been differentiated from the standard only because they cause a characteristic effect in some host plant.

A few strains differ from standard tobacco mosaic virus in many more characters than pathogenicity. Those most studied came from cucumber (*Cucumis sativus* L.)[2], plantain (*Plantago lanceolata* L.)[3] and tobacco (*Nicotiana tabacum* L.)[4]. Like the standard, they contain 6 per cent ribonucleic acid and occur in rigid rod-shaped particles of various lengths but uniform widths, 14·6 mμ for cucumber viruses 3 and 4 and 15·2 for the others[5]. They are precipitated by antiserum prepared against the standard tobacco mosaic virus, but the serological relationship is remote and most of the antigens contained by each one are specific to it[2]. They contain different quantities of some amino-acids, and a given amino-acid may occur in one but not in another[6]. They have different isoelectric points, electrophoretic mobilities and sensitivities to inactivation by ultra-violet radiation[4].

Some of these diverse types have been observed over years and in a range of plants without losing their distinctive properties. Like the standard tobacco mosaic virus, they give rise to variants with different pathogenicities, but otherwise they stay constant. It has been reasonable to assume that, if all have derived from a common ancestor, their current states were reached as the result of many small changes accumulated while they evolved separately, perhaps in different plant species, over a very long time. This may be true, but the behaviour of the virus I have been using shows that a protracted period of evolution is not always necessary to change a strain from one resembling the standard form into one with many distinctive properties.

This virus was discovered causing a mosaic disease of cowpea (*Vigna sinensis* Endl.) in Nigeria[7] and provided the first record of a strain of tobacco mosaic virus that infects leguminous plants systemically, although many cause necrotic local lesions in some varieties of French bean (*Phaseolus vulgaris* L.). When White Burley tobacco seedlings in a glasshouse are inoculated with the virus from cowpea, after first producing necrotic local lesions, they become systemically infected and show symptoms very like ordinary tobacco mosaic. The virus in the systemically infected leaves is closely related serologically to the standard tobacco mosaic virus and resembles it in all properties for which I have tested. The only way in which the two are distinguished readily is by inoculation to some leguminous plants, of which I have mostly used the Prince variety of French bean, when the cowpea virus produces a severe systemic disease and the other has no effect. Varieties of French bean, such as Pinto, which give necrotic local lesions with the standard strain, also give only local lesions with the cowpea virus from tobacco.

The virus obtained from diseased Prince beans is only remotely related serologically either to tobacco mosaic virus or to the cowpea virus obtained from mottled tobacco leaves. Specific precipitates are obtained only when the heterologous antiserum is used much more concentrated than is needed to precipitate its homologous antigen, and the cowpea virus from tobacco probably has fewer than 10 per cent of its antigens in common with the virus from beans. The cowpea virus obtained from the two hosts also has different electrophoretic mobilities, $-4{\cdot}7 \times 10^{-5}$ from bean and $-9{\cdot}4 \times 10^{-5}$ cm.^{2}/sec./volt from tobacco; the virus obtained from bean is also inactivated with much less exposure to ultraviolet radiation. I have not studied their amino-acid compositions, but, by analogy with other strains that have been examined, it can be assumed the two will differ considerably.

Pinto beans inoculated from infected Prince bean show no local lesions, but develop a systemic disease like that in Prince. Tobacco seedlings inoculated from systemically infected Pinto beans give local lesions and a systemic mosaic, but virus from the mottled tobacco leaves produces only necrotic local lesions when returned to Pinto.

Except for the few that affect cucumber, all strains of tobacco mosaic virus produce necrotic local lesions in *Nicotiana glutinosa* L. when growing at usual glasshouse temperatures. The size and character of these lesions vary a little with the age of the plants, and some strains produce rather larger and better defined lesions than others[3]. Cowpea virus obtained from mottled tobacco leaves produces lesions like those produced by standard tobacco mosaic virus; at 20° C. they become visible in 40–48 hr., and they reach a diameter of 3–4 mm. and are clearly defined with a pale centre surrounded by a broad ring of black necrotic cells. The cowpea virus obtained from bean produces lesions that differ more from the standard type than do those produced by any other strain of tobacco mosaic virus I have studied; the lesions are not visible until four days, few reach a diameter of 1 mm. and many are wholly white, though some have incomplete rings of black. The differences are ample to identify small amounts of the tobacco form of the virus in the presence of much more of the bean form, and the production of the tobacco form in plants inoculated with sap from beans can be readily detected by inoculations to *N. glutinosa*.

When tobacco leaves are inoculated, washed thoroughly, and samples taken at intervals to be macerated and inoculated to *N. glutinosa*, the course of virus multiplication can be followed. With sap from tobacco as the inoculum, less virus is recovered 24 hr. after inoculation than an hour afterwards, but newly produced virus is usually detectable 48 hr. afterwards, and at 72 hr. this has already much increased and it continues to do so rapidly. With sap from bean as the inoculum, less virus is usually recoverable 48 hr. after inoculation than an hour afterwards ; lesions begin to form after about 72 hr., and newly produced virus then becomes detectable. This is the bean form, for it produces only small, slowly developing lesions in *N. glutinosa*. It does not occur much more abundantly in later extracts, but at five days extracts from some plants start to produce large, quickly developing lesions, and from then on the amount of such virus in successive extracts increases rapidly with time. The plants of which the inoculated leaves give extracts that contain the tobacco form of the virus are those that later show systemic symptoms. This almost always happens in young seedlings, but becomes less common as the age of plants increases and is rare in those with leaves longer than 15 cm. Young tomato (*Lycopersicon esculentum* Mill.) and *Datura tatula* L. plants are also more likely than old ones to yield the tobacco form of the virus when inoculated from infected beans. Plants that are not members of the Solanaceae can also produce a changed form of the virus. Both forms multiply locally in leaves of sugar beet (*Beta vulgaris* L.), inoculum from beans producing lesions and from tobacco not ; leaves inoculated from beans first yield only the bean form, but after a week yield both.

The tobacco form seems not to be produced in *N. glutinosa* inoculated from beans, and when transferred from one *N. glutinosa* to another the virus has continued to produce only small, slowly developing lesions. From inoculated plants kept in usual glasshouse conditions with a mean temperature of 20° C., very little virus is recovered. *N. glutinosa* inoculated from beans and kept at 37° C. produce much more virus although their leaves show no lesions, but again it all seems to be of the bean form. The loss of pathogenicity towards *N. glutinosa* at 37° C. provides another contrast with the behaviour of the cowpea virus obtained from tobacco, for this, like standard tobacco mosaic virus, produces large chlorotic lesions.

The cowpea virus from beans also behaves differently in tobacco plants kept at the two temperatures. Inoculated leaves of plants kept at 37° C. show no lesions even after many days, although they then contain much more virus than do leaves at 20° C. when lesions develop. All the virus produced at 37° C. seems to be of the bean type and no large lesions are produced by inoculations to *N. glutinosa*. After a week at 37° C., plants moved to usual glasshouse conditions soon show large necrotic rings. Many show only this symptom, and from these the bean form only of the virus has been obtained ; but the young leaves of some later become mottled and they then contain the tobacco form.

I have done little to study the course of infection when bean leaves are inoculated from infected tobacco plants, for the work is complicated by the combination of a small virus content in such inoculated leaves with substances that inhibit infection in *N. glutinosa*. However, it has been possible to show that inoculated bean leaves at first yield only virus that produces large lesions in *N. glutinosa*, but that, after six to eight days, they also yield virus that produces the small, slowly developing lesions.

Changes in the properties of a virus culture when passed through different hosts could be explained simply by postulating that the culture contains two different strains that multiply differentially in the different hosts. My many attempts to gain evidence of such a mixture failed, and several facts conflict with this simple explanation. For example, inoculum from Prince beans, which will produce the tobacco form of the virus when inoculated to many species, produces no large lesions in *N. glutinosa*, and this inoculum can fail to produce the tobacco form when inoculated to tobacco plants in a physiological state that permits this form to infect and multiply when it is added to the inoculum. Also, if two strains are concerned, they must always go together through single local lesions in *N. glutinosa*. I have used extracts from single lesions, produced with diluted inocula, to infect other *N. glutinosa*, and then repeated the process serially. Ten cultures established in this way by four transfers through local lesions, six originally produced by virus from tobacco and four from bean, all resembled the bulk inoculum in their ability to infect both bean and tobacco plants and to show the characteristically different properties when propagated in the two species.

The failure of Pinto beans to become systemically infected when inoculated with extracts from mottled tobacco leaves also tells against the idea that the extracts contain the bean form of the virus. Further, Prince beans inoculated from tobacco take several days longer to show systemic symptoms than do similar plants inoculated from other beans. Similarly, tobacco seedlings show systemic symptoms sooner when inoculated with tobacco sap diluted almost to the infection end-point than when they are inoculated with undiluted sap from infected Prince beans. It seems, then, that inocula from mottled bean or tobacco leaves contain only one form of infective virus, and that the second form occurs only after the first has infected and multiplied in inoculated leaves of the alternative host.

After a prolonged period in either bean or tobacco, during which it has passed through many plants, the virus will still return to the other host, with its behaviour there apparently unchanged. Thus there seems to be a continuity of inherited characters, suggesting a genetic framework that remains stable through considerable changes in the gross properties of the whole virus particles. This could be conferred by the genetic determinants combining in new ways when new particles are synthesized; or the continuity may be only apparent, simulating stability by precisely reversible mutations. Before the second form occurs, some millions of particles are synthesized in inoculated leaves of the alternative host, so opportunity for such rearrangements or changes exists. Equally, though, the genetic material may remain unaltered, and the different forms the virus adopts in different hosts may be equivalents of phenotypic variations, perhaps providing extreme examples of the wide range of different proteins that can combine with the same nucleic acid.

There is much evidence that the multiplication of the standard tobacco mosaic virus is not the precise replication of the infecting particle to give a uniform end-product. In addition to infective variants, distinguishable by their distinctive pathogenicities and usually, though with little justification, called mutations, extracts from infected plants contain a range of specific proteins that resemble the virus in some respects but are not infective[8-10]. Plants systemically infected with the cowpea virus also yield more than one product, and beans appear to contain an unusually large proportion of non-infective protein. Whereas sap from infected beans contains about a tenth of the total specific protein in sap from tobacco, the tobacco sap is more than a hundred times as infective when tested on *N. glutinosa*.

Electrophoretic tests on purified preparations of the bean form, at 2 mgm./ml., show two components, a major one with a mobility of $-4 \cdot 7 \times 10^{-5}$ and a minor one with a mobility of $-9 \cdot 4 \times 10^{-5}$ cm.^{2}/sec./volt, the same as that for the single component detectable in preparations of the tobacco form at 2 mgm./ml. The minor component is about 10 per cent of the total protein; if it were the tobacco form of the virus, it should be detected by inoculation to *N. glutinosa*, for artificial mixtures containing 99 per cent of virus from bean and 1 per cent from tobacco produce the characteristic, large, rapidly developing lesions; but the preparations give only the small, slowly developing lesions. When examined at 20 mgm./ml., purified preparations of the cowpea virus from tobacco also show a small peak, which moves with the same speed as the main peak in preparations of the bean form. No such component has been noted in purified preparations of the standard tobacco mosaic virus, but non-infective proteins with this mobility have been obtained from sap after the infective protein was removed by high-speed centrifugation[10]. As components with the same mobility accompany two strains, only one of which infects beans, there is no need to regard that from tobacco plants infected with the cowpea virus as the bean form of this virus. Rather it is evidence that infection with different strains can lead to the synthesis of materials with common properties. There are other minor components, both in extracts from plants infected with the standard tobacco mosaic or the cowpea virus, with different mobilities, and these provide still further evidence of the range of anomalous proteins that occurs in cells when their metabolism is deranged by infection. It seems that, of the proteins that are synthesized, some may be able to combine with nucleic acid to give stable particles that are also infective, and others not. In the diverse metabolisms of such plants as bean and tobacco, or in tobacco at 20° and 37° C., the nucleic acid will be given opportunities to combine with different proteins. In an environment where the initial infecting particles are of a type that is as stable and as infective as any other that is synthesized, reasonable continuity of properties can be expected; but where they are not, they will soon be superseded by any more stable form that is also better fitted to spread from one cell to another.

The cowpea virus is not unique in its ability to adopt very different guises when multiplying in various kinds of hosts. Suspecting that some other of the reported diseases of leguminous plants might also be caused by strains of tobacco mosaic virus, I tested southern sann-hemp mosaic virus[11] from India. It is not identical with the cowpea virus from Nigeria, but the two behave similarly. The sann-hemp virus can be transferred between Prince bean and tobacco plants, and when derived from tobacco it closely resembles the standard tobacco mosaic virus, whereas when derived from beans it has properties very like those of the cowpea virus from bean.

I thank Mr. R. M. Lister and Dr. S. P. Capoor for sending me the cowpea and sann-hemp viruses, and Dr. A. Kleczkowski for making the electrophoretic measurements.

MODELS FOR METALLO-ENZYMES*

By DR. R. J. P. WILLIAMS
Wadham College and the Inorganic Chemistry Laboratory, University of Oxford

THE importance of metal ions in biological systems has become more clearly recognized in recent years. Tentative explanations have been put forward of the role of the cations in the reactions of enzymes; but many of these explanations lack a reasonable basis when they are compared with the known interactions of cations with simpler organic molecules[1]. The purpose of the present article is to direct attention to such shortcomings and to consider different possible functions which cations could assume in biological systems. To this end the article consists of a critical survey of the properties of complex ions in solution, with special reference to their absorption spectra and stability, followed by a brief discussion of some properties of metallo-enzymes.

Stability of Complex Ions

Sufficient data have been obtained in the study of complex ions in aqueous solution to warrant the general conclusion that no one parameter, such as the electronegativity of the cations, can be dominant in the formation of all the complexes of any one ligand. Even the correlation between a 'corrected' electronegativity and the stability of a wide variety of cations with one ligand should be suspected as

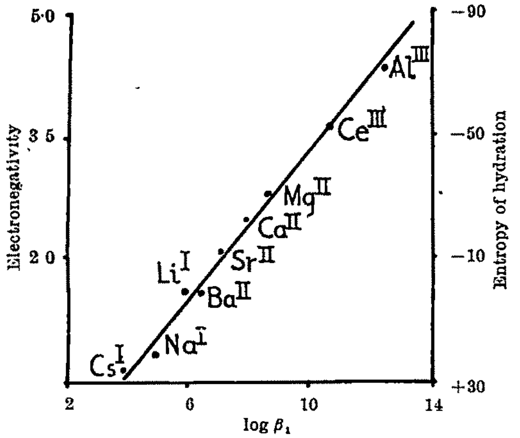

Fig. 1. Relationship between the logarithm of the stability constant for a number of complexes of dibenzoyl-methane with A-subgroup cations and either the electronegativity of the cation or its entropy of hydration

arising rather from the nature of the corrections than from any fundamental importance of the correlation[2]. For example, if the IA, IIA and IIIA subgroup cations of the periodic table are compared in their ability to form complexes with an anion such as dibenzoyl-methane, then the stability of the complexes is as good a function of the entropy of hydration of the cations as of their electronegativity (Fig. 1). The entropy-change of the reaction, a charge neutralization,

$$M^{+} + L^{-} \rightleftharpoons ML$$

is very probably the main 'driving force' in the formation of these A-subgroup cation complexes and is derived from the loss of hydration[3]. The data available at present suggest that reactions of these cations, involving neutralization of charge, are often endothermic[3]. With these same cations the parallel between electronegativity and stability of complexes arises coincidentally from the rough relationship between electronegativity and entropy of hydration. Reasons for this correlation are not difficult to find, for among A-subgroup cations electronegativity $\propto$ ionization potential $\propto$ ionic potential (z/r) $\propto$ entropy of hydration.

On the other hand, the dependence of stability upon the 'electronegativity' of the ground state of the cation in the series

$$\mathrm{Zn^{II}} < \mathrm{Cu^{II}} > \mathrm{Ni^{II}} > \mathrm{Co^{II}} > \mathrm{Fe^{II}} > \mathrm{Mn^{II}}$$

is well established, although the relationship mainly applies to the four-coordinated complexes[3]. There are several exceptional complexes which do not conform to the general pattern, but the exceptions only appear upon six-coordination. Notable among exceptional ligands is orthophenanthroline, which forms a particularly stable ferrous complex. The ferrous ion does not have the ground-state electronegativity in this complex. Now although on an absolute basis the ferrous ion does not form a more stable complex with phenanthroline than does the cupric ion, the relative differences in stability in the presence of a second ligand, for example, glycine, are such that ferrous can appear as a phenanthroline complex while cupric appears as a glycine complex in a mixed solution of both ligands. Analysts frequently employ a combination of two such reagents. They refer to the second one as a masking reagent. Such masking reactions are particularly important in biochemistry, for they lead to a selective combination of cations and ligands, not on an absolute basis of stability, but on the relative basis of competition of excess ligands for all kinds of cations. Inspected in this way, it seems at least probable that in a biological system at pH 7·2, zinc should be found held in complexes with sulphide, iron in complexes with imines, and magnesium found mostly with oxyanions[1].

Bonding in Transition Metal Complexes

The bonding in complexes of transition-metal cations is now known to be more complicated than was at first thought[4]. The general suggestion that π-bonds as well as σ-bonds control stability has been increasingly supported since it was first introduced by Pauling[4,6–8]. The relevant molecular orbitals for both types of bond can now be given, and it can be shown theoretically and experimentally that there is need to include two sets of such interactions: first, those described by Pauling, in which an empty orbital of either the ligand or the cation acted as an acceptor of electrons from its coordination partner; and second, the further bonds between half-filled d orbitals of the cation and the full levels of the ligand necessitating the partial use of anti-bonding states (Fig. 2). The total stability will be a function of the proper mixture of the two interactions. A change of emphasis is now required when relating the stability of a complex with ionization potentials or electronegativities, for the latter do not truly reflect the energy-levels of a cation in the field of a ligand, that is, the electronegativity is a function of the bonding. In particular, the original discussion given by Irving and Williams of their stability series is seen to be incorrect, in that it ascribed all bonding differences to acceptor characteristics of the cations, without the essential consideration of the ways in which both acceptor and donor properties of cations were influenced by the ligand. Discussions by Fernelius and his co-authors[3] are similarly in error. A proper consideration of the effect of the ligand-field[8] explains why the six-coordinate complexes of nickel are equally stable with the cupric complexes, an observation not in accord with the earlier theories. The Irving–Williams series is an empirical order applicable to complexes in which replacement of water takes place in four or fewer positions in the coordination sphere of the cation[3].

Absorption Spectra of Complex Ions

The absorption bands of chelating ligands such as 8-hydroxy quinoline are affected by cations to but a

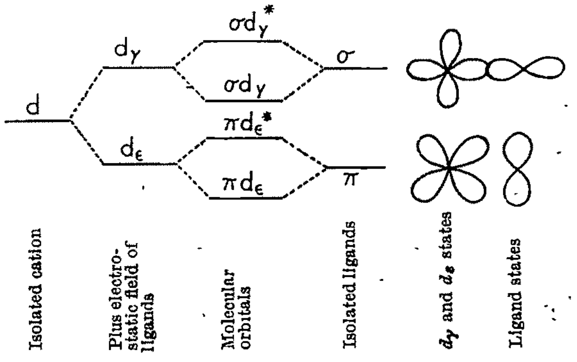

Fig. 2. Stark splitting of d-states together with the formation of bonding and anti-bonding orbitals between the split d-states and states of the ligand. The diagram also illustrates the way in which the orbitals overlap

slight extent. The shifts appear to be in the order $Zn^{II} < Cu^{II} > Ni^{II} > Co^{II} > Fe^{II} > Mn^{II}$ and $Zn^{II} > Mg^{II} > Ca^{II} > Ba^{II}$. These orders clearly reflect the 'electro-negativity' of the cations[9]. In their complexes with ligands such as porphyrin and phthalocyanine, however, the 'electronegativity' of all the cations is not that of their ground states, for several of them are in states of lower spin-multiplicity; for example, in nickelous porphyrin and cobaltous phthalocyanine. These and other cations such as palladous have an enhanced electronegativity in porphyrin and similar complexes, and the order of the shifts of the ligand absorption bands becomes[9]:

$$(Fe^{II}) > Ni^{II} > Co^{II} > Cu^{II} > Zn^{II} > (\overset{*}{Fe}{}^{II}) > Mn^{II}$$

The ferrous complex has different properties depending upon the solvent in which the complex is dissolved. In dioxan the absorption band is at a wave-length and of an intensity similar to that of the zinc complex; but in pyridine the absorption spectrum closely resembles that of a nickel complex. It can be said that the electronegativity of the ferrous ion is a function of its coordination—in pyridine the ferrous complex is diamagnetic, but it is paramagnetic in dioxan.

Not all the absorption bands of complex ions are to be described as modified ligand bands. In the ferrous, cuprous and cobaltous complexes of diimines, for example, terpyridyl, there are absorption bands which can only be attributed to transitions of the cation electrons bound in molecular orbitals which include the ligands. The influence of substituents in the ligand upon the position of the absorption bands in these complexes further suggests that the excitations involved are partial electron transfers to the ligand[9]. Now while there are many examples of partial charge-transfer bands in which charge is increased on the ligand, there are many bands in the absorption spectra of the complexes of oxidizing cations which can be confidently attributed to partial transfer of electrons to the cation. Of particular interest are the bands in ferric complexes generally, and in particular with phenanthroline and porphyrins[9].

All the absorption bands discussed so far are intense. Certain bands of transition metals, $d - d$ spectroscopic transitions, are usually weak. It is now thought that these d states can become mixed with energy states of the ligand, forming the molecular orbitals referred to in the above discussion of stability, both through π- and σ-bonding (Fig. 2). The formation of such molecular orbitals can be used to account for features of the band position and band intensity in the spectra of complexes[7,8]. In biological systems, however, it is not possible to study the weak bands because of the dilution of the cation and of the presence of other strong bands.

Biological Systems

The subject-matter under this heading will be divided into two parts. In the first, the major concern is the way in which cations, which are, in general, loosely held by the enzymes, can change the rates of reaction of the enzymes with substrates. A brief reference to the Lewis acid properties of cations is used as an introduction.

From a comparative examination of a large number of model systems, the catalytic effect of a cation in acid-base reactions has been shown to parallel the stability of the complexes of the cations with the activated state of the substrate[10,11]. The formation of a complex with the normal state of the substrate can be detrimental to reaction rather than favourable to it. In the first transition series, the catalytic efficiency of cations follows the Irving–Williams order:

$$Zn^{II} < Cu^{II} > Ni^{II} > Co^{II} > Fe^{II} > Mn^{II}$$

in all the model systems examined so far. However, in not a single biological system has this order of catalytic efficiency been observed[1]. The differences between the models and the biological systems are obvious. The models present one (or two) possible chelating groups to the cation. The protein/substrate system of a biological reaction presents very many different possible chelating centres. In acid-base reactions certain types of chelation will be effective and others detrimental. It would appear that electronegative cations, combining preferentially with sulphydryl groups, generally form chelates detrimental to acid-base reactions, and that therefore such cations as lead, mercury, copper and nickel are often enzyme poisons. The best cations for the catalysis of acid-base reactions, which involve substrates which can coördinate through oxygen only, are magnesium and manganese. If the substrate contains nitrogen-coordinating groups, on the other hand, then zinc, cobaltous and ferrous are often equally effective. If the cation function is not to bind the substrate but is merely to provide a method of bringing a coenzyme and a protein together in a correct stereochemical alignment, then the competition that must be considered is that between the chelating centres of the coenzymes, of the various sites of the protein, and of the substrates. Consideration of these possibilities reveals the ways in which one cation acts as an inhibitor, another as a catalyst[1], or even the way in which a cation can be an activator of an enzyme at low concentration and an inhibitor at high concentration[12].

The second major influence of cations in biological systems is upon oxidation-reduction reactions. For example, the reactions of iron porphyrin proteins are of the utmost importance in biological systems. They carry oxygen and transport electrons. However, there is a complete parallel group of copper enzymes which perform similar functions, but these proteins contain no porphyrin. Again, there is a group of cobalt complexes, not found in biological systems as yet (apart from vitamin B_{12}), which can show certain of the reactions of the biologically important copper and iron compounds. From this evidence I tentatively conclude[13] that the function of the ligand in all these complexes is to induce similar properties in three dissimilar cations. The absorption spectra of the complexes of these cations reveal that the property induced is the willingness of the reduced states of the cations, cobaltous, ferrous or cuprous, to donate d_ε electrons into π-orbitals of their ligands[9]. This donation of d_ε electrons accounts for the double bonding in oxygen, carbon monoxide, nitric oxide and cyanide complexes. The d-electrons are also donated to any other unsaturated ligand to which the cations are bound, for example, to porphyrin in a ferrous porphyrin complex. When ferrous is bound to both porphyrin and carbon monoxide, there is a competition between the two ligands for the d-electrons. Now the absorption of light by the ferrous porphyrin results in enhanced donation of electrons to this ligand, as in the models (see above), that is, the removal of d-electrons from the cation. The removal of d-electrons must weaken bonding to

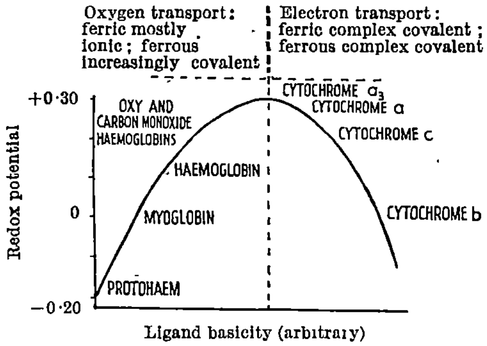

Fig. 3. Proposed relationship between ligand basicity (or electronegativity) and the oxidation-reduction potentials of their iron complexes. The basicity, plotted on an arbitrary scale, is used in preference to the electronegativity because of the difficulty of assessing the electronegativity of the ligand

carbon monoxide. The sensitivity of carbonyl ferrous porphyrin complexes to light absorption can now be understood. Many other features of the absorption spectra and properties of the ferrous porphyrin proteins can be explained in terms of the spread of the *d*-electrons over the porphyrins[13].

The iron and copper proteins also have in common oxidase properties. Small differences in coordination bring about the large differences in reactivity between the oxidases and the oxygen-carrying proteins. For example, cytochrome *b* is not a very different protein from hæmoglobin—they contain the same ferrous porphyrin. There is, however, the major difference that the ferrous ion is only diamagnetic in hæmoglobin when combined with oxygen, while the ferrous ion in cytochrome *b* is always diamagnetic. Only when the ferrous ion is diamagnetic is it a good electron donor. In the cytochrome, then, ferrous donates electrons to the porphyrin (the only ligand which is a good acceptor) and is readily oxidized. In oxyhæmoglobin, on the other hand, the major electron acceptor is oxygen (oxygen restricts electron donation to the porphyrin) and therefore prevents the hæmoglobin entering oxidative reactions. A detailed study of the absorption spectra and paramagnetism of these and other iron complexes[13] as compared with the model systems gives very strong support for these views. In fact, a study of the absorption spectra and the oxidation-reduction potentials of the whole series of hæm-proteins known in biological systems reveals steady gradations in properties which can be correlated with the change in the function of the proteins. Some of the properties are referred to in Fig. 3. Other series of ferrous complexes show similar changes in the same properties (for example, the phenanthrolines and the simple porphyrins), but in these cases the series obtained are the same as those formed by gradations of basicity (or electronegativity) among the ligands of the complexes. It seems likely that the hæm-proteins are also arranged in a series of changing ligand basicity (or electronegativity) as in Fig. 3.

MOVEMENTS IN THE IONOSPHERE

THE Royal Astronomical Society held a Geophysical Discussion on November 25 on the subject of irregularities in the ionosphere and their horizontal movements. Most of the British workers on the subject were present, and the meeting took the form of a free discussion on a series of points introduced by the chairman. Those taking part were J. A. Ratcliffe (in the chair), W. J. G. Beynon, E. N. Bramley, B. H. Briggs, P. C. Clemmow, M. Dagg, J. W. Dungey, E. T. Eady, J. S. Greenhow, A. Hewish, I. L. Jones, M. Ryle, R. S. Scorer, K. Weekes and M. V. Wilkes. The main points in the discussion are summarized below, and the initials in brackets refer to the speakers.

Horizontal drifts of irregularities of electron density in the ionosphere are detected at different heights by radio methods as follows: between about 80 and 100 km. by the drift of meteor trails; between about 90 and 130 km. (*E* region) by observation of the fading on close-spaced receivers; between about 200 and 300 km. by similar fading observations, and also by the observation of large-scale travelling 'ripples' which show as 'kinks' on *P′*(*f*) or *P′*(*t*) ionospheric records; and above 400 km. by the fading, or scintillation, of the radio waves received from radio stars.

Briggs and Spencer have given a summary of the knowledge obtained by these methods[1]. In the *D* and *E* regions there is a mean drift, with a velocity of about 50 m. sec.$^{-1}$, which changes with the seasons and on which is superimposed a drift with a velocity of about 30 m. sec.$^{-1}$ that rotates twice in 24 hours. In the lower *F* region the east–west component of the velocity is towards the east by day and towards the west by night. The north–south component by day is towards the pole in summer and towards the equator in winter; by night it is small. The ripples observed in the *F* region usually have a quasi-wave-length of 100–200 km. and their deformation in the vertical direction is such that, if there were real concave mirrors of this extent, their depth would be 5 km. or less. The irregularities responsible for the scintillation of radio stars are markedly anisotropic, and are probably a few kilometres in extent in their smallest dimension.

The discussion brought out the fact that there is a well-established height-variation of the phase of the 12-hourly rotating component in the *E* region. This has been observed (J. S. G.) by working with meteors, the height of which can be measured, and by observing (I. L. J.) the fading of waves on two neighbouring frequencies, which are reflected from somewhat different heights. The results of the two sets of observations agree, and indicate that the phase advances by about 5° km.$^{-1}$ for heights between about 85 and 130 km. The meteor observations (J. S. G.) also indicate that the phase alters with seasons, and both sets of observations show that the magnitude of the rotating velocity-component increases with height. Although at greater heights movements of irregularities in the electron density will not necessarily follow the movements of the air (P. C. C.), or of the surrounding electrons, there is every reason to suppose that meteor trails, at levels near 90 km., indicate the movements of the air itself. Since the deductions made from observations of meteor trails are consistent with those made on the fading of reflected waves, it is reasonable to suppose that the latter, also, indicate air movements. It is then interesting to inquire what sort of movement might be expected from theoretical considerations.

The theory of semi-diurnal tides in the atmosphere (K. W., M. V. W.) leads us to expect a rotating component of the drift velocity of the order of the observed one in magnitude, but until now the phase has not been as expected. The new observations that the phase varies with height could be explained in terms of a temperature gradient, but it is difficult to explain why the phase changes with the seasons.

Since in the *E* region the electron movements seem to be determined by the air movements, it is interesting to consider what air movements might be produced by other than 'tidal' forces. It was pointed out (E. T. E., R. S. S.) that horizontal temperature gradients might be great enough to produce eddies, and that waves produced by the flow of air over obstacles near the ground could probably extend upwards into the *E* region. It was also pointed out (R. S. S.) that the technique of observing noctilucent clouds has been improved recently and that observations on a larger scale can be expected in the next few years.

The most interesting piece of new information (B. H. B.) about the lower *F* region was that simultaneous measurements made on large-scale ripples, and on the small-scale irregularities which produce fading, show that both these irregularities travel with the same speed. If this observation is correct, it has important implications for the theory, since the present tendency is to suppose that the 'ripples' represent the travel of a distortional wave-motion through the electrons, and that the movements of the small-scale irregularities are produced by the joint effect of electric and magnetic fields.

Spencer[2] has shown that the scintillations of radio stars are produced by irregularities of electron density, at heights above 400 km., which are elongated and are oriented along the direction of the Earth's magnetic field. These irregularities produce an anisotropic diffraction pattern at the ground, of which the direction of elongation changes through the day and through the year as the position of the star changes. The observations have now been continued (I. L. J.) for a complete year, and the expected results have been obtained. A more detailed analysis of the results has shown that the length of the irregularities is about three or four times their breadth, and not about ten or twenty times as was originally supposed. Because the irregularities are elongated, any measured drift velocity is biased towards a direction perpendicular to the long axis. In practice, only the component of the true drift in this direction can be observed. By making observations (M. D.) on two radio stars almost simultaneously, two velocity components can be derived and hence the true direction of drift can be deduced. In this way, it has been shown that the true drift is towards the south-west; not simply towards the west as previously supposed.

It is difficult to account for the occurrence of these elongated irregularities, which are detected only at night and at heights greater than 400 km. It was once thought (Ryle[3]) that they were produced by interstellar matter attracted to the Sun and intercepted by the Earth on its dark side. Recent work (A. H.) has shown that the irregularities, as evidenced by radio stellar scintillation, do not occur at the same time at Washington, D.C., Cambridge and in the Gold Coast. Scintillations are twice as common at sunspot minimum as at sunspot maximum. Theory suggests that, at these heights, movements of electrons would not follow movements of the air, so that simple turbulence is not a likely cause for the irregularities. If, however, there was turbulence in the *E* layer for any reason, it was suggested (M. D.) that the resulting irregular electrostatic field might be transferred, along the magnetic lines of force, to the *F* region in such a way as to produce irregularities of electron density there. In support of this idea it was stated that increased scintillations are sometimes accompanied by a magnetic disturbance, but there is no one-to-one correlation. It was also suggested (J. W. D.) that a type of electromagnetic disturbance could perhaps travel from the *E* to the *F* region along a line of magnetic force, in such a way as to produce irregular variations in the *F* layer.

Attention was also directed (M. R.) to recent studies on the counterglow by workers in the U.S.S.R. They have interpreted this as a result of streaming of the upper atmosphere away from the Earth on the night side. This atmosphere is supposed to be repelled by the Sun, much as a comet's tail is repelled. It would tend to stream along the magnetic lines of force, and possibly with an irregular density, and might be responsible for the scintillations.

OBITUARIES

Sir Arthur Trueman, K.B.E., F.R.S.

WHEN Sir Arthur Trueman died on January 5 at the early age of sixty-one, in his house in London, his passing left a gap in many circles created by his wide intellectual interests and attainments. By profession he was a geologist, and few have attained greater eminence or contributed more to the science by research, by teaching, or thorough administration. His early training at the High Pavement School and later at University College, Nottingham, laid the foundations for his subsequent eminence as a palæontologist concerned with various aspects of the faunas and of the stratigraphy of Carboniferous and Jurassic rocks. These researches were carried out during an unusually full and rich academic career, which commenced with his appointment as lecturer at University College, Cardiff, in 1917, where he came under the influence of Franklin Sibly. This was followed by appointment to the chair of geology and geography at Swansea (1921), and the subsequent tenure of chairs at Bristol (1933) and at Glasgow (1937–46).

Trueman's researches, though closely related, fall into three main categories largely resulting from and conditioned by the experience gained from his detailed and original morphological, ontogenetic and phylogenetic studies on ammonites. Accounts of the evolution of several families of ammonites were followed by similar studies on gastropods and the lamellibranch *Gryphaea*. Characteristically, Trueman recognized the implications of his palæontological discoveries in terms of their practical application towards a fuller understanding of Jurassic chronology and of their usefulness in zonal subdivision of these rocks in the field. Thus concomitant work described the palæontology of the Lias rocks from Lincolnshire and South Nottinghamshire to Somerset and Glamorganshire.

There followed that part of his work concerned with appreciation of the fundamental conceptions involving genera and species, of populations and of variability, and of the impact of such considerations upon taxonomy. His contributions to the more philosophical aspects of palæontology ranged among other topics, from lineage and orthogenesis, to a reconsideration of the species concept in palæontology, and culminated during his revision of the Coal Measures Non-marine Lamellibranchs (1927) in the application of biometric techniques to a study of variation in fossil communities and to the use of statistical investigations in detailed correlation. Work by Trueman, and others who have since extended his conceptions, has led to radical changes in outlook and added considerably towards evaluation of fundamental processes in evolution.

Trueman's later work dealt with the palæontology and with varied aspects of the stratigraphy of the British Coal Measures. The purely palæontological studies of the Coal Measures non-marine lamellibranchs from South Wales soon enabled him to indicate their practical applications in the identification of coal seams, and resulted in a zonal subdivision of the South Wales Coal Measures in 1927, leading to a suggested correlation of the British coalfields (1933). The detailed application of this zonal scheme to every major British coalfield, and the utilization of the accruing evidence in exploration within coalfields, or during boring for extensions or for new fields, by Trueman, independent workers and by officers of the Geological Survey bear witness to its efficacy. Indeed, this subdivision has formed the accepted method of presentation in all important papers and memoirs since its inception, and has contributed largely to a rationalization of Coal Measures stratigraphy, as summarized by Trueman in his presidential addresses to the Geological Society of London. The publication of a Palæontographical Society Memoir on the Coal Measures non-marine lamellibranchs in collaboration with Dr. J. Weir marks still further an important permanent record of widespread researches which constitute a major contribution to geological science.

Acknowledgment of his work by election to the Royal Society followed in 1942; the Geological Society of London awarded him the Bigsby Medal (1939) and the Wollaston Medal (1955).

Sir Arthur was energetically concerned for the welfare of geological science at all levels and published a number of books, in general illustrated by himself, and which were of interest to the layman, the school pupil or the student. However, his interests and knowledge were considerably more widespread and embraced many aspects of the educational field and of its organization and its contacts with science and industry. This knowledge made him a welcome member of many committees, such as the Elliot Commission on educational problems in West Africa, the Advisory Council on Scientific Policy, and as chairman of the Geological Survey Board.

Those who were fortunate to come under his influence either as students or staff regarded him with respect and affection, for his kindness, integrity and sympathetic understanding made him a friend in whom one felt complete confidence. His charm of manner and keen sense of humour, combined with a remarkably quick grasp of problems and wise judgment in their solution, convinced one of his very personal interest in every member of his department, student and staff alike. No student ever sought Trueman's help or advice in vain. He was always ready to discuss work and ideas and contrived to make all feel their ideas were interesting and their results important. As a leader he was a deep source of inspiration and encouragement, and possessed that inestimable gift of putting a person at ease. His enthusiasm and zeal were combined with a vital and ceaseless energy which he imparted to others; his lucidity of mind and exposition made him a great lecturer and superb teacher, in the lecture theatre, and above all in the field.

This remarkable combination of wide university experience, achievement, leadership, organizing ability and high moral integrity led to his appointment as deputy chairman of the University Grants Committee in 1946, and its chairman in 1948. In this office, at a time of critical importance in the developments of the British university system, Trueman contributed much by his knowledge, influence and wise counsel. Unfortunately, his period of office was limited, for he fell ill late in 1952 and soon afterwards resigned.

During the last years of his life Trueman struggled with great and uncomplaining fortitude against increasing physical disability, his mind alert and active, his sense of humour unimpaired; and during this time, with indomitable spirit he wrote parts of, and edited contributions for, his last book, "The Coalfields of Great Britain", a project which had been in his mind for many years.

Sir Arthur is survived by Lady Trueman and their son, E. R. Trueman. Lady Trueman's companionship, help, understanding and encouragement contributed greatly towards his many achievements, and her unselfish devotion during the later years enabled him to face his disability with great courage.

LESLIE R. MOORE

Prof. Duncan Leitch

THE tragically premature death of Prof. Duncan Leitch at the age of fifty-two, a week after that of his friend and colleague, Sir Arthur Trueman, came as a shock even to those friends who knew of his grave illness.

Leitch was a graduate of the University of Glasgow and served there as assistant and lecturer in geology until, in 1947, he succeeded Prof. T. Neville George in the chair of geology at the University College of Swansea.

Leitch's main scientific work was concerned with the palæontology and stratigraphy of the Coal Measures. He collaborated with me in zoning the

Scottish Coal Measures by the successive assemblages of non-marine bivalves that are fossilized in these rocks. Afterwards he used the zones in elucidation of an obscure section of Coal Measures in Arran, and gave accounts of variation in several groups of these fossils, notably of Lower Carboniferous and Namurian *Naiadites* which are peculiar to Scotland and are doubtless forerunners of the numerous and more widely distributed guide fossils of this genus in the Coal Measures. His most notable work on this line, however, was the admirably detailed biometric description of variation in a community of *Anthraconaia* [*Anthracomya*] from the Central Coalfield of Scotland, prepared with the help of Dr. R. A. Robb, which made an important contribution to taxonomic method in the study of these highly variable animals, and explained various anomalies in their vertical distribution within the Coal Measures.

At Swansea Leitch had established a research team to continue the study of these principles and their application to field-problems, especially in the structurally difficult measures of Pembrokeshire; but his premature death has inevitably deferred the fulfilment of this work.

For several years he was secretary of Section C (Geology) of the British Association.

Leitch was a kindly, friendly man who loved company, an attribute that was reflected in his happy relations with students in laboratory and field. He leaves a widow and young son. J. Weir

---

Sir Richard Redmayne, K.C.B.

Sir Richard Redmayne, who died on December 27, was born at Low Fell, County Durham, in 1865. He was the son of John Marriner Redmayne, of Low Fell—a lover of the fine arts and no mean painter in water colours and a devout Christian: attributes fully inherited by his son. His grandfather, Giles Redmayne, built and endowed Brathay Church in Westmorland and was complimented on its structure by the poet Wordsworth.

Sir Richard served his apprenticeship at the Hetton Collieries under William Armstrong, a famous mining engineer who had been apprenticed to the celebrated John Buddle, the 'father of the Coal Trade' and intimate friend of George Stephenson of locomotive fame. At one period in his training he rose at 2.30 a.m., and walked a mile and a half to the mine, which he descended at 3.30 and came out at 10.30. In the afternoon he attended the office to write reports and do other administrative work. He also studied at the Durham College of Science—now King's College, Newcastle upon Tyne. He became an under-manager and in 1891 left England to undertake mining operations in South Africa. In 1893 he was appointed manager of a group of collieries at Seaton Delaval. On that occasion the Rev. C. H. Boutflower—afterwards Bishop of Tokyo and later of Southampton—wrote as follows:

"Turn on the buzzer, blow the horns, bang all the tubs together!
Let every Gall'way neigh response, each driver crack the leather!
Oh happy day—let Seaton say—and happiest news to tell of all
Dick is become our Manager of Mines at Seaton Delaval."

In 1902 Sir Richard was appointed professor of mining at the University of Birmingham and, writing as one of his first students, I can say that all those who studied under him will honour his memory for his great kindness and the hospitality of his home by the then Mrs. Redmayne, who was the ideal hostess. Sir Richard retired from the chair at Birmingham to become the first H.M. Chief Inspector of Mines at the Home Office, and I was very fortunate in serving him as private secretary for two years. His appointment caused a little jealousy among a few of the then senior inspectors, but the justification of his selection was soon evident. Very early he had to investigate and report upon some of the largest colliery explosions which have occurred in Britain. At that time the late Sir William Garforth had conducted large-scale experiments at Altofts Colliery, where there had been a serious explosion, demonstrating the explosive nature of coal dust and the possibility of neutralizing its nature by the application of stone dust. Sir Richard decided immediately to strengthen the regulations relating to safety and drafted a Bill which became the Coal Mines Act, 1911. This Act, based on practical and scientific knowledge, foresight and common sense, is, at the moment, still in operation. This fact indicates the soundness of its structure. In my opinion this Act was Sir Richard's *magnum opus*. Its enforcement resulted in diminishing rapidly the loss of life from such disasters.

Another potential source of danger existed—the danger of open sparking and shock from the application of electricity in mines; and a committee of experts was appointed to consider the inadequacy of the Electrical Special Rules of 1905. The committee consisted of Sir Richard as chairman, Mr. C. H. Merz and Mr. Robert Nelson, who had been appointed the first H.M. Electrical Inspector of Mines. New rules were established and Mr. Nelson enforced them with tact to the great benefit of the industry.

After the firedamp explosions at the Jamage Pit in North Staffordshire and at Cadeby Colliery in Yorkshire (where the Divisional Inspector and eighty-seven others were killed), which were caused as the result of spontaneous combustion, the Home Secretary set up a departmental committee with Sir Richard as chairman to inquire into the circumstances in which spontaneous combustion of coal occurs in mines, its causes and the means of preventing it, and a Blue Book was issued. A code of rules was afterwards drawn up on the organization for rescue and aid in the case of accidents in mines. Now there are numerous rescue stations and trained men in all the coalfields of Britain.

It is perhaps true to say that no man in his profession has filled so many posts and performed such various duties. Sir Richard was a member of three Royal Commissions. He was chairman of the Board for Mining Examinations for many years and was external examiner in mining for the Universities of London, Birmingham, Wales and New Zealand, and examiner for the Camborne School of Mines, the Board of Education and the City and Guilds of London. Sir Richard was held in such high esteem by H.M. Civil servants that he was elected for thirty-three years in succession as president of the Institution of Professional Civil Servants. He was also a past-president of the Institutions of Civil Engineers and of Mining and Metallurgy.

This appreciation might appear to be overloaded if a complete list of the offices Sir Richard held were given. He had been a director in a number of colliery and other companies and for many years acted as a consulting mining engineer. He found time, however, to produce text-books on colliery working and management and the valuation and rating of coal and mining properties. He had a wonderful memory, and his book on "Men, Mines and Memories" is a most fascinating and instructive work. In 1914 he was made K.C.B., and in 1918 he became a chevalier of the Legion of Honour; he was also a companion of the Order of St. John of Jerusalem.

Though such a distinguished and highly gifted man, his personal friends will perhaps remember him chiefly for his sense of humour and great personal charm. He married Edith Rose Richards, daughter of Thomas Picton Richards, of Swansea, in 1898; she died in 1942. There were two sons and two daughters of the marriage. One son died as the result of a motor-car accident. The three others survive him.

GRANVILLE POOLE

NEWS and VIEWS

Physics at Bedford College, London: Prof. H. T. Flint

THE retirement of Prof. H. T. Flint from the Hildred Carlisle chair of physics in Bedford College, University of London, constitutes a severe loss to the scientific personnel of the University, for he was a man of exceptionally wide interests. Not only was he a most able teacher whose text-book (with B. L. Worsnop) on experimental physics in the laboratory has for decades been a standard work for honours students, but also his contributions to quantum theory, to relativity and to field theories generally have formed a continual stimulus to workers on these subjects. In addition, his training in medicine and the possession of a medical degree have made him a valued referee for numerous bodies requiring advice on medical physics. His colleagues in the University of London are immensely indebted to him for the many administrative duties which he has generously undertaken as chairman of the University of London Board of Studies in Physics and chairman of the Examining Board. A graduate of the Universities of Birmingham and London, much of his life was spent as reader in physics at King's College, London, when the Wheatstone chair was held successively by Sir O. W. Richardson, Sir Edward Appleton and Sir Charles Ellis. His appointment to the chair at Bedford College in 1944 enabled him to use his long-proved abilities, during the difficult post-war decade, for the development of both theoretical and experimental physics at Bedford College to the maximum possible capacity. He leaves Bedford College in the knowledge that he will not be saying farewell to his innumerable friends, who will continue from time to time to seek that advice which has been so freely and generously given in the past.

Prof. H. O. W. Richardson

PROF. FLINT is succeeded by Prof. H. O. W. Richardson, who has held the chair of physics at University College, Exeter, for the past three years. A son of Sir O. W. Richardson, he graduated at King's College, London, and proceeded to the Cavendish Laboratory, Cambridge, where he received the Ph.D. degree for his researches on applications of the cloud-chamber technique to problems in radioactivity. After further research work at King's College and Bedford College in the University of London, he was appointed a lecturer in the Department of Natural Philosophy at Edinburgh under Prof. N. Feather. It was there that he carried out his important theoretical and experimental studies on the β-ray spectrometer. Brought up in the atmosphere of scientific research, possessed of an original and inventive mind and personality, and with wide experience of a variety of laboratories, Prof. Richardson has much to contribute to the development of physics teaching and research at Bedford College.

Editorship of *Discovery*: Mr. William E. Dick

MR. WILLIAM E. DICK has resigned from the post of editor of *Discovery* after just over twelve years in the chair. During that period, scientists and laymen alike have watched the considerable improvements made in that journal, for Mr. Dick has become established as one of Britain's leaders in the presentation and interpretation of science to the public (see also *Nature*, 172, 1028; 1953). He has now undertaken the editorship of the newly established journal *British Chemical Engineering*, the first issue of which will be published in May (Drury House, Drury Lane, London, W.C.2).

Dr. Anthony Michaelis

DR. ANTHONY MICHAELIS succeeds Mr. Dick as editor of *Discovery*. Dr. Michaelis obtained his degree in chemistry at the Imperial College of Science and Technology. After several years spent in industrial research laboratories, he joined the headquarters staff of British Intelligence Objectives Sub-committee and during the period 1945–48 he edited the series of the Sub-committee's overall reports. He has since specialized in scientific films, and has devoted particular attention to the use of cinematography as a research tool. He is closely connected with the Scientific Film Association, and has served on the executive committee of that organization (see also p. 298 of this issue). At the Bristol meeting of the British Association in 1955 Dr. Michaelis was mainly responsible for organizing the successful scientific 'film festival', during which some forty films were exhibited.

Russell H. Chittenden (1856–1943)

RUSSELL HENRY CHITTENDEN, the 'father of physiological chemistry in the United States', was born at New Haven, Connecticut, one hundred years ago on February 18, 1856, of a family that had emigrated from Kent in 1639. Almost his entire scientific career was spent in the city of his birth. In 1874, when he was eighteen, he was placed in charge of "the first definitive laboratory of physiological chemistry in America for the instruction of students" in the Sheffield Scientific School at Yale University. In the following year he obtained the degree of B.Sc. with a thesis on glycogen and glycocoll in the muscular tissue of *Pecten irradians*, which was published in the *American Journal of Science and Arts*. It was the German translation in Liebig's *Annalen der Chimie* that gained him entrance into Willy Kühne's laboratory at Heidelberg in 1878. Four years later he was appointed professor of physiological chemistry in Yale University (the first chair of its subject in the United States). From 1898 until 1922 he was director of the Sheffield Scientific School. His most important work was concerned with the protein element in human nutrition in the days when Carl von Voit's dietary standards were generally accepted; as a result of experiments performed during 1902–3 on himself, his colleagues, students and volunteers from the United States Army, Chittenden showed that good health, physical vigour and nitrogenous equilibrium can be maintained on levels of protein intake considerably below those specified by Voit. In 1909 he served on the Remsen Referee Board to report on the toxicity of sodium benzoate in foods, and after the First World War, together with Graham Lusk, he represented the United States on the Inter-Allied Scientific Food Commission in London, Paris and Rome. His best-known books are "Physiological Economy in Nutrition" (1904) and "The Development of Physiological Chemistry in the United States" (1930). Many honours came his way. In 1896 he was elected president of the American Physiological Society, which office he held for a record number of nine years, and in 1906 the first president of the American Society of Biological Chemists. A scrupulously neat person, who possessed an unerring flair for attracting worth-while pupils, Chittenden died at New Haven on December 26, 1943, in his eighty-seventh year.

Lobachevski and Non-Euclidean Geometry

THIS year marks the centenary of the death of the Russian mathematician, N. I. Lobachevski, on February 24, 1856. He was born in 1793 at Nijni Novgorod, and at the age of eight became a scholar at the Gymnasium at Kazan, where he made remarkable progress in the study of mathematics and classics. When fourteen years of age he entered the University of Kazan and spent the next forty years there, first as a student, then as a professor and finally as rector. Lobachevski played a major part in the development of the University and undertook a great deal of teaching and administration. In spite of this, he was still able to give time to mathematical thought and succeeded in creating a new field of mathematics. For more than two thousand years the question remained unsolved as to whether Euclid's parallel postulate is an independent axiom or can be deduced from other axioms. Lobachevski was the first to settle the question by constructing a non-Euclidean geometry, based on the hypothesis that through a fixed point there is an infinity of lines parallel to (that is, not meeting) a given line. This situation occurs on a pseudosphere. In 1855 "Pangeometry", the completed works of his mathematical life, was published; it was written in French and Russian and had been dictated because of his blindness.

Inland Waterways in Britain

THE Minister of Transport and Civil Aviation announced in the House of Commons on February 1 that he has appointed a Committee of Inquiry into Inland Waterways with Mr. Leslie Bowes as chairman. The other members of the Committee are Messrs. J. Corbett, G. C. Godber, H. E. Hopthrow, W. A. Muddell (chairman of the Land Drainage Committee of the River Boards' Association), F. Ritchie (National Parks Commission), M. Rowe and J. Wilson. The Committee will consider and report on the future of the system of inland waterways in Britain and propose any measures necessary to achieve: (i) the maximum economic use of the system; (ii) the future administration of and financial arrangement for inland waterways which cannot be maintained economically for transport purposes, having regard to requirements of public health and safety, and the facilities which these waterways can provide for recreation, water supply, land drainage and dispersal of effluents; and (iii) the conversion of canal sites to other purposes when this is desirable and practicable. The Committee will also consider the present law relating to the closing of waterways to navigation, and make recommendations.

Permanent Exhibition of Scientific Instruments in London

A PERMANENT exhibition of instruments made by a selection of the hundred and forty member firms of the Scientific Instrument Manufacturers' Association of Great Britain was opened on February 9 by Sir Norman Kipping, director-general of the Federation of British Industries. The exhibition is housed at the Association's headquarters at 20 Queen Anne Street, London, W.1, and though not intended to be public, it is open to all those interested in scientific instruments, especially visitors from overseas. Besides being a centre where visitors can see a representative selection of instruments, the display will also serve as a meeting-place for makers and users of instruments in Britain. An extensive catalogue library is being built up. Since it is impossible to give space to all member firms at the same time, a rota system has been worked out so that each member will have a chance to exhibit, and at the same time the character of the display will change constantly. In opening the exhibition Sir Norman said that the output of the British instrument industry is valued at £60 million a year, of which £15 million is exported. Stressing the importance of instruments in all branches of industry, he said that the fact that of the fifty thousand workers in the instrument industry in Britain, two thousand five hundred are engaged on research and development work augurs well for the future.

Shortage of Science and Engineering Graduates in British Industry

A LETTER sent to Mr. Iain Macleod, Minister of Labour, signed by Sir Norman Kipping, director-general of the Federation of British Industries, reaffirms the concern of the Grand Council of the Federation at the continuing shortage of science and engineering graduates. It not only urges that industry is handicapped by the general shortage, but also refers to the growing effect of the selective deferment from National Service which is granted to such graduates who take up government or government-supported jobs related to national defence; the effect in practice is that these men remain in the same sort of job and are lost to industry indefinitely. The Federation regards the situation as so serious that, while appreciating the difficulties of exempting all science and engineering graduates from National Service, it urges the Government most strongly to grant deferment where requested to all science and engineering graduates with first- or second-class honours degrees who take up employment in industry generally as well as in government establishments or on government-sponsored projects, and to continue deferment so long as they remain in such employment. It estimates that the entire annual output of science and engineering graduates in Great Britain is 1·5 per cent of the number of men eligible for National Service, and that for one reason or another some 50 per cent of the latter are never called up.

Babel: An International Journal of Translation

The first number of *Babel*, an international journal of translation, has appeared, published by the International Federation of Translators, with the support of Unesco, the Director-General of which contributes a foreword (1, No. 1; 1955. Pp. 40. From the Federation, 16 rue Pierre Charron, Paris; 5*s*. an issue, or 17*s*. annual subscription). It represents the results of the first efforts, after the phase of organization, of the Federation, which was founded in 1953. The most important article in the present issue is that of R. W. Sumpelt outlining the general policy of the Federation and its affiliated organizations with regard to scientific and technical translating and indicating some of the problems with which it is proposed to deal in *Babel*. These include the recording of scientific and technical terminology on an international scale; the improvement of dictionaries and other lexicographical aids; and research in semantics and linguistics to decide what terms would be improved by standardization, and whether standardization should further cope with entire patterns of expression and of thought. Questions on costs of translation will also be considered, and, besides authoritative studies on these and other subjects, reports on current activities and meetings of other organizations of interest to the Federation are also invited. The present issue outlines the translation programme of representative works of Unesco and includes an article by Dr. S. D. Limaye discussing some basic aspects of scientific translation in India and the building up of an Indian scientific vocabulary.

British Rainfall during 1953

Under the title "British Rainfall 1953" is published the ninety-third annual volume of the British Rainfall Organization and the thirty-fifth as a Meteorological Office publication (M.O. 588; pp. 216. London: H.M.S.O., 1955; 25*s*. net). Each volume in the series summarizes the rainfall measured during a year at more than five thousand stations, many kept by voluntary observers, in Great Britain and Northern Ireland. The year was on the whole a dry one over most of the country, with amounts of less than 20 in. and less than four-fifths of the average over much of England and Wales. Over north-west Scotland, it was rather wet with up to six-fifths of the average. At Pontefract the total was only 15·43 in. against an average of 23·3 in. The low rainfall over England and Wales was due to the winter months at both ends of the year being dry; the summer was rather a wet one. January was notably dry with a general average of only 1·4 in. over England and Wales and was part of one of the driest winters on record. The heaviest fall in one day was one of 6·5 in. on November 26 at Cwm Dyli, Snowdon. Some very heavy falls of rain occurred in the heavy thunderstorms of June 26, on which day at Eskdalemuir, Dumfries, 2·09 in. was measured in half an hour—the heaviest known fall recorded in the country in that period of time—and 3·54 in. in fifty-five minutes; on the same day 1·72 in. fell in fifteen minutes at Nelson, Lancs. Mr. J. Grindley contributes a useful tabulation, county by county, of the very heavy rainfalls observed since 1860 in periods up to two hours. They are those of, or exceeding, the "Noteworthy" category, which ranges from 0·43 in. in less than five minutes to 1·19 in. in two hours. These show the heaviest fall in ten minutes to have been 1·3 in. at Chagford, Devon, on September 23, 1927, in an hour 3·63 in. at Maidenhead, Berks, on July 12, 1901, and in two hours 4·8 in. at Churchstoke, Montgomery, on June 26, 1895.

Psychological Tests for Accident-Proneness and Industrial Proficiency

Memorandum No. 31 of the Medical Research Council, entitled "Psychological Tests for Accident Proneness and Industrial Proficiency" (pp. 30. London: H.M.S.O., 1955; 2*s*. net), is a reprint of the Industrial Health Research Board reports (Nos. 38, 55, 68, 74 and 84) on accidents, and its appearance is very welcome. The author of the summary, E. G. Chambers, has studied this problem with the late Prof. Greenwood, Miss E. M. Newbold and Eric Farmer for many years. He notes in the introduction that the investigations reported have extended over fifteen years and have involved more than four thousand subjects and the use of more than thirty different tests. The object of the study was to discover what relationship existed between the test scores of the subjects tested and the recorded accidents. It was hoped that some idea would be gained of the measurable psychological qualities involved in proneness to sustain accidents, with the ultimate practical object of choosing tests to help in the selection of workers for dangerous occupations. Whenever possible, records of industrial efficiency were obtained so that the effect on the proficiency of selection for accident-proneness could be demonstrated. The reports give details of the tests, together with the inter-relations of the tests and their prognostic value, and the present memorandum is a summary of the main conclusions described in the five reports beginning in 1924. No new material is incorporated, and the data are not treated in any new way. Of course, since the publication of these reports, statistical techniques have improved and now the experiments would be planned differently; but a fairly extensive knowledge of recent work makes one realize that the present-day techniques have done little to increase our knowledge. The subjects tested included dockyard apprentices, naval ratings, London and provincial bus-drivers and various groups of trainees. The tests included sensori-motor, æstheto-kinetic, mental and intelligence, physiological, and nervous stability tests. Details of the tests and the precautions taken are given. The outbreak of war in 1939 terminated this research.

Statistical Review of England and Wales

The General Register Office has recently issued the "Text Volume" of the "Registrar General's Statistical Review of England and Wales for the Year 1952" (pp. 256, 8*s*. net) and the "Medical Tables, Part 1", for 1954 (pp. 375, 12*s*. 6*d*. net). (Both published by H.M.S.O., London.) There are few changes in the presentation of the tables: the most important is the inclusion of tuberculosis notifications in the table relating to notifiable diseases, data which have hitherto only been given in the annual reports of the Chief Medical Officer to the Ministry of Health. There have also been minor changes in the method of classifying hospitals for the chronic sick, which may affect the comparability of local death-rates. The text for 1952 consists of the usual commentary on population movements in that year. There were no violent changes to report: fertility remained at a stable level, and the concentration of childbearing in the early years of marriage continued. The report brings out the remarkable increase in the married population; in the age-groups 15–19, 20–24 and 25–29 the proportion of women who were married exceeded that in 1938 by 83, 49 and 21 per cent, respectively. An interesting report on marriages by method of solemnization shows that 13·6 per cent of the 1952 religious marriages were celebrated according to Roman Catholic rites against 9·1 per cent in 1934, the last year for which figures were collected. Civil marriages as a proportion of all marriages increased from 28·4 per cent to 30·6 per cent in the same period. The mortality section of the text includes a detailed analysis of cancer mortality.

Vitamins: Memorial Essays to Sir Edward Mellanby

The January issue of the *British Medical Bulletin* (12, No. 1; from the British Council Medical Department, 65 Davies Street, London, W.1; 15*s*.) is a memorial number to Sir Edward Mellanby, the late secretary of the Medical Research Council. As the article on him and his work by Sir Charles Harington, director of the National Institute for Medical Research, so clearly shows, his death deprived British medicine of one of its most influential figures. The number consists of a series of essays on the vitamins, written by experts, which were originally planned by a committee with Sir Edward as chairman, and he himself intended to contribute to it. Now it appears as a memorial to him—a fitting memorial, for it was in the field of vitamins that Sir Edward did such notable work. It is fitting, too, that one article describes the work of the Accessory Food Factors Committee and Mellanby's influence on the work of this Committee. It is impossible to select, from a list of sixteen articles, all written by leading authorities, any that excel the others. The whole issue is valuable; and those interested in any way in vitamins will find that the summaries given of recent work, and the bibliographies that accompany each article, are sources of information which will add to their understanding of a volume of work that is now so extensive that few, if any, can follow all its many aspects and applications. An excellent photograph of Sir Edward, taken in Lucknow, accompanies the number.

Recording of Animal Sounds: Conference in Pennsylvania

The commercial development of tape recorders during recent years has fostered a great deal of scientific research in the recording of sounds made by animals. Unfortunately, the comparison of results by different workers is very difficult: the printed word in a journal is obviously inadequate; the physical analysis of sounds into 'pictures' has little meaning to biologists, and it is not practicable to convert the picture back to the original sounds for retesting; and even the exchange of actual tapes between workers may be useless if the associated machines are of different types. To make a start on these problems a conference will be held during April 16–19 in the United States at the Pennsylvania State University, at which it is hoped to reach agreement on acceptable procedures for recording animal sounds and start a repository of tapes. The first day of the conference will be devoted to reports of research on animal behaviour in which sound-recording techniques have been used, given by the following: Prof. Donald Griffin (Harvard University), Dr. R.-G. Busnel (Laboratoire de Physiologie Acoustique, France), Prof. F. Möhres (University of Tübingen) and Prof. R. J. Pumphrey (University of Liverpool). The remaining days will be devoted to informal discussions on recording techniques and standards. Further information on the conference can be obtained from Prof. H. Frings, Department of Zoology, University Park, Pennsylvania.

University of London: Appointments

Dr. D. R. Cox, visiting research professor in the University of North Carolina, has been appointed to the University readership in statistics tenable at Birkbeck College.

The title of reader in the University of London, in the subjects indicated, has been conferred on the following in respect of the posts that they already hold: Dr. E. J. Harris (biophysics), University College; Dr. Leonard Saunders (pharmaceutical chemistry), School of Pharmacy; Dr. John Sutton (geology), Imperial College of Science and Technology.

Royal Astronomical Society: Officers

The following have been elected officers for 1956 of the Royal Astronomical Society: *President*, Sir Harold Jeffreys, Plumian professor of astronomy in the University of Cambridge; *Vice-Presidents*, Dr. A. Hunter, Dr. J. Jackson, Prof. A. C. B. Lovell, Dr. R. A. Lyttleton (*Geophysical Secretary*); *Treasurer*, Prof. L. M. Milne-Thomson; *Secretaries*, Prof. C. W. Allen, Prof. H. Bondi; *Foreign Secretary*, Sir Harold Spencer Jones.

Announcements

Dr. Claude E. Shannon, research mathematician at the Bell Telephone Laboratories, Inc., has been appointed visiting professor of electrical communications at the Massachusetts Institute of Technology. He will be associated with the Institute's Research Laboratory of Electronics, and will lecture on advanced information theory, based on his recent research at the Bell Laboratories. Dr. Shannon's work in mathematical theory has led to the development of maze-solving machines, and more recently he has been studying problems in probability, such as the design of reliable machines consisting of unreliable components.

The Ergonomics Research Society is arranging a symposium on "Human Factors in Road Transport", to be held in the University of Bristol during April 16–19. The first session will be a general one, though most of the papers will deal with some aspect of visibility, and the second and third sessions will be devoted to driver behaviour and physiological aspects, respectively. The fee for the symposium is 5*s*. for members of the Society and 35*s*. for non-members. Accommodation can be booked at the Manor Hall, one of the University halls of residence. Further information can be obtained from H. Murrell, The Miners' Arms, Priddy, Wells, Somerset.

Erratum. The article on "Structure of Semi- and Non-crystalline Materials" in *Nature* of January 21 contains a reference to a paper by Dr. E. J. W. Whittaker (p. 122, col. 2, line 5 from bottom); in this reference, for "chrysolite" read "chrysotile".

THE NUFFIELD FOUNDATION

REPORT FOR 1954–55

THE tenth report of the Nuffield Foundation, covering the year ended March 31, 1955*, the first year of its third quinquennium, has been published, and records that allocations from income totalled £681,397 during the year, a figure only exceeded when, in 1952–53, the Foundation made its second large five-year allocation to the National Corporation for the Care of Old People. Expenditure for research and experiment within the United Kingdom was maintained undiminished at £445,079, in the year 1954–55 more than a quarter of the expenditure on grants was spent on helping research workers and students overseas. While during 1943–49 this expenditure averaged about £53,000 a year, during 1949–54 the average was £120,000; the report notes that the Foundation's contribution to date of just over £1 million to travelling and research grants and other projects in the British Commonwealth overseas may be the largest private contribution from Britain to the finance of organized academic and professional relations within the Commonwealth, and it also expresses the Foundation's hope that other private resources may be available to enter a field where the opportunities are so great and so rewarding.

Grants within the United Kingdom during the same twelve years have included £875,000 for medical research (including £295,000 for rheumatism); £586,000 for biological research; £614,000 for research in the physical sciences; £684,000 for projects in the social sciences; £37,000 for architectural studies; and £32,000 for agricultural research. Grants for the care of the elderly and research on problems of ageing have totalled £970,000; for fellowships and scholarships for residents of the United Kingdom, £292,000; and for miscellaneous projects, £277,000.

For the year under review, the projects overseas have taken the largest single share (£133,732) of the year's grants, including the creation of a new unit at the University College of East Africa, Kampala, for research into education in Africa; the building of new halls of residence for students at the Imperial College of Tropical Agriculture, Trinidad; £20,940 over four years for Prof. L. C. Beadle's programme of research on tropical swamps; research in Africa which necessitates the participation of trained non-European research workers; marine biological studies in South Africa; and assistance to the newly formed *Journal of the Anatomical Society of India.* The second largest share (£112,541) went to biological studies in the United Kingdom, and more than half of these grants were renewals or additions to earlier ones. Grants to medical research in the United Kingdom totalled £106,560, nearly half of this, including £22,060 from the Oliver Bird Fund, being for research into rheumatism, while fellowships, scholarships and similar awards accounted for £102,566, nearly two-thirds being for residents overseas in the Commonwealth.

A feature of this report is the evidence that the projects which the Foundation has fostered are coming to fruition, and this is to be found in the tribute paid to the important scientific results which have now come from two earlier grants through the University of Oxford. In August 1955 Dr. Dorothy Crowfoot Hodgkin, as a result of the detailed X-ray analysis of crystals of complex compounds that are of interest in biology and medicine, conducted by her small research team, was able to announce the solution of the crystal structure of a degradation product of vitamin B_{12}, and with it the structure of almost the whole of the chemically unknown part of the molecule. The second result is the discovery, made by Dr. R. G. Macfarlane and associated workers as part of a long-term programme on blood-diseases, of a method of extracting highly concentrated anti-hæmophilic globulin from ox and pig blood for the treatment of hæmophilia, injection of which into hæmophilic patients undergoing surgery, skin-grafting and dental extraction invariably completely prevented abnormal bleeding.

Of the seventeen grants for biological research made during the year, about half the total was for new grants, more than half of which were for research in departments of botany. New grants include £16,000 over five years to the University of Liverpool for studies on the chemistry and microbiology of the polyphenolic types in the soil; £15,000 over three years to the University of Oxford for research under Dr. Honor Smith into certain immunological reactions of the central nervous system; and £6,000 over three years to University College, London, for electron-microscopical studies of the central nervous system. A grant of up to £3,000 over three years has been made to the University of Oxford to assist Prof. C. D. Darlington's work on chromosomes and £2,500 over three years to the University of Southampton to enable Prof. W. T. Williams to engage two additional research workers for his study of etiolation in plants. Additional grants include a further £5,005 over the remaining two years of the university quinquennium in support of Prof. J. F. Danielli's investigations at King's College, London, into the nature of differentiation and the factors controlling it, particularly the relative importance of nucleus and cytoplasm; a further £22,500 for four years to the Nuffield Institute for Medical Research, Oxford, to support Mr. H. B. Parry's research on pregnancy toxæmia of sheep; and a further £1,550 a year for the two years 1955–57 and £235 for equipment to the University of St. Andrews for Prof. H. G. Callan's work on comparative endocrinology.

On the recommendation of the Department of Scientific and Industrial Research, the Foundation has decided to spend up to £35,000 to finance a pilot aeromagnetic survey to ascertain whether the extensive use of such surveys in Great Britain would be justified on economic and technical grounds. A grant of £7,200 over three years has been made to Birkbeck College, London, to support Dr. A. D. Booth's work on mechanical translation, and the Foundation is also providing a sum of up to £7,000 over three years to the University of Oxford to meet the running cost of the Archæological Research Laboratory, after which, it is understood, the University is prepared to take over the whole recurrent cost. A progress report from the Foundation's Division for Architectural Studies records that during 1954 a pilot study on the use of space, services and equipment in research laboratories was made in two of the major establishments of the Agricultural Research Council and that the first appointments have been made to the two postgraduate fellowships in architecture, tenable within the Division.

---

* The Nuffield Foundation. Report for the Year ended 31 March, 1955. Pp. 125. (Tenth Report.) (London: Nuffield Foundation, 1955.)

The major part of the year's grants for medical research went for further fundamental research in the chronic rheumatic diseases, and the Oliver Bird building, which houses the clinical and laboratory research of the Rheumatic Unit, Northern General Hospital, Edinburgh, was completed and opened during the year. New grants for medical research included £17,500 (including £1,250 for capital expenditure) to the Frenchay Hospital, Bristol, to finance current expenditure over five years on Dr. R. M. Norman's research into the causes of certain types of mental deficiency; and £5,000 to the University of Durham for a survey of Tyneside industry by the Nuffield Department of Industrial Health. A further grant of £5,000 over three years was made to University College Hospital Medical School, London, for the continuation and development of Dr. N. Smyth's work on the application of electrical techniques in medicine, in particular for the study of the womb in childbirth, which has already made a contribution to the safety of mother and infant; and an additional £4,000 was offered to the Oxford Regional Hospital Board to enable the project on the relation between physique and behaviour, with special reference to psychiatric disorders, at the Warneford and Park Hospitals, to continue for another year.

Most of the allocation for social research and experiment was to complete the grant of £100,000 additional to the permanent endowment of Nuffield College, Oxford. New grants include £2,500 a year for three years for a bibliographical programme in the social sciences, aimed at the production of good bibliographical tools by elaborating a series of consistent schemes or recipes which will facilitate the provision of abstracts or bibliographies in the social sciences. It will include a survey in London of the adequacy of existing library and research facilities for social scientists. Another new grant of £3,300 a year for three years was made to the University of Oxford in support of Lady Hall's empirical research into the distributive trades; £2,600 a year for five years has been given to the Shoreditch Project Committee for launching an experiment in preventive social work, and a research scholarship of £1,250 a year for three years to Dr. V. L. Allen for his proposed study at the London School of Economics and Political Science of the role of trade unions in Britain during the past thirty-five years. A final grant of £3,000 has been made to the Institute of Statistics, University of Oxford, for completion of the national survey of incomes and savings.

A grant of £8,000 over four years was made to St. Bartholomew's Hospital Medical College, London, to support Prof. K. J. Franklin's research into the physiology of ageing, and one of £5,000 over two to two-and-a-half years to Lord Beveridge to enable him to carry further his history of prices and wages in England. A miscellaneous project of some wide interest is the inquiry into the best means of assisting the learned periodicals. A sum of £43,750 over five years has been allocated for this purpose; in the meantime the British Academy and the Royal Society have been informed that a sum of £8,000 a year will be available over the next five years to be spent on the support of primary journals in primary subjects, and that up to a further £750 a year will be available for the payment of any necessary professional advisory fees on such questions as printing economy, publication and distribution. The distribution of the grant will be entrusted to two special committees, one for periodicals in the humanities, and one for scientific periodicals. With the taking over by the Kent County Council of the Mersham reception centre for deprived children, established with the help of the Caldecott Community, the balance of the Foundation's grant has been allocated to establish an experimental remedial education centre.

Of the eighteen new projects in the Commonwealth overseas, besides those already noted may be mentioned: £5,200 to the University of Adelaide for studies, by electrophoresis diffusion, of substances and systems of biological interest; £6,800 to the Australian National University, Canberra, towards the first three years cost of a five-year research project on post-war immigration into Australia; £3,200 to the University of Sydney in support of a small medical and anthropological expedition to the high country of New Guinea; £3,700 over three years to the Cawthron Institute, Nelson, for research on symbiotic association in New Zealand plants, with special reference to their nutrition and growth on soils poor in certain nutrients; and £3,000 a year for three years to the University of Otago for a combined investigation there and at Canterbury Agricultural College, Lincoln, into endocrine problems of lactation.

During the year twenty-two awards were made to residents of the United Kingdom and forty-three to residents of the Commonwealth overseas (including the first five Canadian study-grants for short-term research in the United Kingdom). Eleven awards were made under the scheme of visiting lectureships and special grants, open to residents of the whole Commonwealth, and fifteen appointments were made in 1954 under the Royal Society and Nuffield Foundation Commonwealth bursaries scheme.

SCIENCE AND TECHNOLOGY IN WESTERN GERMANY

THE brief review of the scientific recovery of Western Germany, compiled by Mr. K. H. Lauder, scientific attaché to the British Embassy in the Federal Republic and issued by the Department of Scientific and Industrial Research*, is of great interest both to the scientist and technologist. It outlines in the first place, very briefly, the action taken by the United Kingdom authorities from 1946 onwards to assist the rehabilitation of academic science in Western Germany—action with which the Department of Scientific and Industrial Research has been associated from the start, primarily by financing the preparation of reports by German scientists; nearly thirty such reports, which are listed in an appendix to this review, were later issued in Britain as "Sponsored Research (Germany) Reports". To this work a generous tribute is paid in a letter from Prof. Otto Hahn, president of the Max-Planck-Gesellschaft zur Förderung der Wissenchaften, Göttingen, and the review itself shows the success which has attended this action.

---

* Department of Scientific and Industrial Research. A Brief Review of Science and Technology in Western Germany. Pp. viii+103 (London: H.M.S.O., 1955.) 4s. net.

Secondly, the review gives a concise but authoritative picture of the present organization of science and technology in Germany and the way in which, following the almost complete collapse of scientific and technological activity, this has been rebuilt on modern lines. Its successive chapters, dealing with physical sciences and technology, electrical engineering and electronics, engineering (except electrical), chemical sciences and technology, metals, biological and medical sciences, agriculture and forestry, and productivity in industry, facilitate an accurate appreciation of the strength and weakness of Western Germany's position in world technology, outside the restricted or prohibited fields of aerodynamics, radar and nuclear science; and it shows how serious a challenge Western Germany offers to British technology now that the post-war phase is over and Western Germany has emerged as a sovereign power. Thirdly, while it is in no way intended as a reference book, the review brings together in convenient form much useful information on universities, technical and scientific institutions in Western Germany, research expenditure and the like.

Damage to research institutions in Western Germany at the end of the Second World War is estimated to have averaged 61 per cent of the total destruction, equipment was non-existent and scientific research and technological development were at a standstill. From the nucleus of scientists collected at Göttingen in 1946 has grown the Max-Planck-Gesellschaft, which to-day is probably the most significant non-industrial research organization in Western Germany, and, except in fields highly significant in defence, the recovery of science is now practically complete. On an average the rebuilt research establishments and the buildings and equipment of the many new research institutes appear to be better than corresponding ones in Great Britain. Staffing, however, has been a major problem, though the rebuilding of research institutes has been accompanied by an intensive programme of education in the expanded universities and colleges of technology, including generous subsidies for travel abroad, to repair the gaps in scientific knowledge and man-power.

Government expenditure on scientific research in academic and independent research organizations is estimated at more than DM. 600 million during the past financial year and is still increasing, while industry is spending a like sum in its own research establishments, estimated at about 5 per cent of turnover for the chemical industries and 1 per cent for engineering: expenditure by the Farbenfabriken Bayer, by the Badische Anilin- und Soda Fabrik and by the Farbwerke Hoechst is estimated at about DM. 40 million each, and the former is completing a fourth new laboratory for research and development at Leverkusen at a cost of DM. 15 million. Siemens und Halske (now reported to be the third largest electrical undertaking in the world) has recently completed a new research and development laboratory at Munich to accommodate twelve hundred research workers. Considerable effort is devoted to fundamental research, and the mounting cost of research is encouraging co-operative research.

The review suggests that the gap between scientific research abroad and that in Western Germany is narrowing and that in some fields, such as electron microscopy, Germany is abreast, if not ahead, of the rest of the world. The chemical industry has put a very large amount of money into research during the past three or four years, and Western Germany has also gone far to organize a healthy growth of its chemical engineering industries. A research association has been set up and long-term plans have been made for the provision of research institutes, each concentrating on specific fields. The first of these, at Aachen, is already operating, and others are planned at Darmstadt, Munich and Karlsruhe. Much attention is being given to rationalization, and several teams have visited the United States to study American methods in automation. After allowing for the heavy social burdens carried by industry, it is estimated that the real cost of labour is 90 per cent of that in the United States. Some fundamental research has already been carried out in aerodynamics, radar and nuclear science, and now that these fields are open, extensive programmes of applied research have been planned.

It is probable that, although somewhat elaborate, the organization of science and technology in Western Germany is now better than ever. The major scientific bodies are as follows: the Deutsche Forschungsgemeinschaft, or German research council; the Stiften-Verband für die Deutsche Wissenschaft e.V., a society of influential men, chiefly industrialists, concerned with collecting money from industry for the support of science; the Max-Planck-Gesellschaft zur Förderung der Wissenschaften e.V.. a re-creation of the Kaiser Wilhelm society; the Deutsche Verband Technische-Wissenschaftlicher Verein; the Arbeitsgemeinschaft Industrielles Forschungsvereinigungen, co-ordinating the activities of twenty-three industrial research associations; the Nordsheim Westfälische Arbeitsgemeinschaft für Forschung; and the Deutsche Gesellschaft für Dokumentation. The work of the Deutsche Forschungsgemeinschaft is described at some length. Besides its research programme, for which the Federal Government's current grant runs at DM. 10 million a year, it makes an annual grant of DM. 1 million to about thirty-five scientific libraries on condition that their literature is available to scientists generally and also makes grants for the printing of *Habilitationsschiften* (probationary treatises embodying the results of original research) and *Fortsetzungswerke* (revised or supplementary works), particularly those that may have a very limited circulation.

An increasing tendency to contract research is noted; two and a half years ago the Battelle Memorial Institut für Deutschland e.V. was established at Frankfurt am Main, beginning work in December 1953, and the establishment of an agency for contract research, known as the Vermittlungsstelle für Vertragsforschung e.V. is planned. Although Western Germany has no government department specifically charged with looking after scientific research, most ministries support research in some form or other, and grants proposed in the Federal Budget for 1955 for scientific research and technological establishments totalled more than DM. 164 million, as against DM. 75·9 million in 1954. In 1954, moreover, taking into account contributions from State governments, from district councils and municipalities and from other donors, the total contribution for non-industrial scientific research, including scientific teaching, totalled DM. 663·8 million compared with DM. 391·6 million in 1950. Independent calculations indicate that the average cost of research in Western Germany per head of staff is about DM. 9,000, and about four times this figure per head of qualified staff. Among Government research institutions may be mentioned the Physikalisch–Technische Bundesanstalt, which conducts research on standards of physical quantities and on equipment, for example, where safety is involved, and the Bundesanstalt für Mechanische und Chemische Materialprüfung.

There is no exact equivalent in Germany of the Royal Society, the body most nearly corresponding to it in pre-war days, the Deutsche Akademie der Wissenschaft in Berlin, being now under the control of the East German Government. There are, however, four academies of science in Western Germany; and, with the founding of the Johannes Gutenberg University at Mainz in 1946 and of the Free University of Berlin in 1948, and the conversion, in 1945, by addition of a humanistic faculty, of the College of Technology, Berlin-Charlottenburg, into the Technische Universität, Berlin, there are now in the Federal Republic of Western Germany and the Western Sector of Berlin sixteen universities, eight 'Technische Hochschulen' (colleges of technology with university status), and eight other colleges with university status but more highly specialized. The Technische Hochschulen aim to achieve a blending between teaching and applied research, and much of the undergraduate research is undertaken in industry itself. Many industrial research institutes are associated with these Technische Hochschulen, either as part of a teaching department or as separate research institutions.

At the end of the Second World War the German patent system had ceased to exist; but after protracted discussions a Western German patent office was re-established in October 1948, moving later to new premises in Munich, and in 1953 the number of patent applications was about 7 per cent higher than in the whole German Reich in 1938, the trend being towards a further increase. The emphasis on applied research is growing. Even in general terms this is an impressive achievement; and, of all the achievements in particular fields that are summarized in the review, it is difficult to select examples that illustrate more emphatically the extent to which Western Germany is prepared to make the scientific research effort upon which to-day the economic and political strength of any country depend. It might be added, however, that Western Germany can again supply the bulk of its own requirements for scientific instruments and that these are finding a growing market abroad, that the Institute of Radiation and Nuclear Physics at the University of Bonn plans to instal a 30-MeV. synchro-cyclotron, that there are estimated to be eight thousand ultrasonic generators in Western Germany, and that there has been intensive development of the electron microscope which is widely used as a research tool. In electrotechnology there have been notable developments in power technology, in the field of heavy equipment, in electrical instruments of all kinds and in electronics, particularly the development of computers.

In mechanical engineering the traditional interest in machine-tool design has been maintained, and major developments are proceeding in railway transport. Gas turbines are being investigated for heavy road vehicles and stationary power plants, and extensive use of newly developed building aids and techniques has enabled the building industry to achieve a building-rate second only to that of Sweden. Much attention has been given to road research, while in chemical industry the Gelsenkirchen firm, Bergwerke A.G., has commenced production of dicyclopentadiene based on raw benzole, and the Krupp Kohlenchemie G.m.b.H. the Fischer–Tropsch synthesis of hard paraffins. Rheinpreussen A.G. has extended its plant for propyl and butyl alcohol to a capacity of ten thousand tons annually, and Farbenfabriken Bayer, Leverkusen, is continuously improving its methods of producing dyestuff intermediates and general textile chemicals, including preservatives, detergents and emulsifiers, and is taking a great interest in automatic processing. Germany now claims second place in world plastics production, and a new research centre at Darmstadt is investigating the structure of plastics and setting up methods of testing. In the biological and medical sciences the impact of new physical techniques is evident, and some of the most significant researches are those on the fundamental chemical processes of cell metabolism, biochemical mechanisms and chemotherapeutics. Much effort is directed to the solution of Germany's difficult agricultural problems, and particular attention has been paid to soil humus, potato cultivation and systemic insecticides.

ELECTRON MICROSCOPY OF FIBRES

During January 3–4 the Electron Microscopy Group of the Institute of Physics held what was originally intended to be a small specialist conference on the electron microscopy of textile and other industrial fibres, in the Department of Textile Industries of the University of Leeds. The response, in attendance and papers offered, showed that the experiment was amply justified. In all, more than sixty delegates, eight from overseas, attended, and eighteen papers were read and discussed. There were three half-day sessions, devoted to techniques, protein fibres and cellulose fibres, respectively.

In the first session O. C. Wells (Cambridge) described the scanning electron microscope developed at Cambridge, and gave examples of its use for studying fibre surfaces. Whether the scanning microscope or the reflexion microscope (which was used by J. A. Chapman (Manchester) in a study of abraded nylon fibres) will ultimately 'corner' this particular field was the subject of much speculation; neither is yet capable of the resolution of the conventional transmission instrument, but each has certain advantages. On the whole, opinion seemed to be that the added complication of the scanning instrument would, at present, prevent its competing effectively with the other, but further developments will be eagerly awaited by microscopists.

Replication techniques were discussed by D. G. Drummond (Manchester) and by L. Oster, J. Sikorski and H. J. Woods (Leeds). Both schools find two-stage replicas most satisfactory in practice; Drummond has been working with the polystyrene/carbon process[1], but the Leeds workers still favour their silver/SiO technique, which they are using to study merino wool and nylon surfaces. Drummond stressed the desirability of reducing preparatory techniques to a routine capable of being followed by unskilled assistants; but the Leeds team seemed to imply that this was crying for the moon, since in their experience replication is an art which can only be learned by experience.

Ultra-thin sectioning is at last becoming a major tool in fibre microscopy, and a number of papers were devoted to investigations in this field. A. O. T. Charles and J. Sikorski (Leeds) have studied the polymerization of embedding methacrylates, an important process in the preparation of specimens for sectioning; they discussed the advantages and drawbacks of the technique they favour, namely, polymerization by ultra-violet light. P. Chippendale (Manchester) showed sections of wool, rayon and nylon fibres and illustrated how skin and core effects can sometimes be detected in the man-made fibres. Although some details of the cellular constitution of the cortex could be seen in his wool sections, the results emphasized that normal wool has only slight variations in electron density between histological components in the cortex. G. E. Rogers (Cambridge) presented two papers which described what were technically the most beautiful micrographs shown at the conference. His sections of the wool follicle, although enormously superior in resolution, could be compared for clarity with the best results of the histologists using light microscopes, who seem to be left with few distinctive tools other than stains and the polarizer. Enthusiasm for sectioning must, however, be tempered by the fact that the examination of normal mature natural fibres by this technique has not yet produced any very remarkable results, and it remains to be seen whether the argument, that sectioning is the only correct technique because it does not involve degradation, is still valid. A point of view which found support was that the use of sectioning or disintegration in conjunction with controlled chemical treatments is still one of the most fruitful fields of investigation.

In the second session Sikorski and Woods pointed out the difficulty of reconciling the macrofibrillar type of structure observed in the follicle of a wool fibre with the occurrence of extended microfibrillar sheets in disintegrated fibres. They suggested that keratinization might involve the stabilization of a microfibrillar texture which is not yet obvious in the matrix regions of the cortical cell in the follicle, and the uniplanar linking together of the microfibrils to form sheets. They reported that different methods of attacking the disulphide links in keratin (for example, by reduction or oxidation) may lead to distinctive disintegration products when specimens are prepared for examination by the electron microscope. M. S. C. Birbeck and E. H. Mercer (London) described sections of hair in their study of the cuticle layer. They now believe, on the basis of histochemical experiments, that the endocuticle is non-keratinous in character; they also emphasized the importance of the cell membranes both in the cuticle and the cortex of the fibre. An interesting suggestion was that in human hair, where the cuticle cells have large overlaps, the epicuticle seems to be tucked in beneath the scale which it is covering; this feature is less obvious in wool fibres.

D. Burton, R. Reed and M. J. Wood (Leeds) discussed the hydrothermal shrinkage of leather, a phenomenon of great technological importance in the control of leather manufacture. In the early stages of hydrothermal treatment, tanned collagen fibrils swell and assume a helical form, while the cross-striations come closer together. Similar structures, with left- or right-handed twist, also occur during the heat treatment of native collagen fibrils. The fibril is therefore considered to be a cross-helical array of polypeptide chain bundles, these being of variable chemical composition and hence sensitivity towards heat. Tanning forms cross-links between the two helical arrays, while shrinkage involves the relative movement of the cross-helical structures.

K. M. Rudall (Leeds) showed pictures of the thin ribbon-like units of the ootheca of the praying mantis. Structurally, these protein sheets are important in that they possess a modified α-type structure with preferred orientation in the transverse plane; although the polypeptide chains are parallel to the length of the ribbon, a feature of the electron micrographs is the appearance of striations inclined to the length at an angle of approximately 22°. A. B. Meggy and J. Sikorski (Leeds) described microcrystals of the two forms of polyglycine [see also p. 326 of this issue]; the most notable micrographs showed that polyglycine II crystallizes in hexagonal laminæ, in agreement with the trigonal structure proposed recently by Crick and Rich[2]. Growth spirals are observed in the crystals, and the growth steps correspond roughly, but not exactly, with the mean chain-length. Although both forms of polyglycine can absorb considerable quantities of dye (for example, orange II), there is no direct evidence either from X-ray or electron microscope studies as to where the dye is located in the structure.

The final session started with a paper by E. Frei and R. D. Preston (Leeds), who showed micrographs of serial sections of conifer wood tracheids, in which the spiral angle of the microfibrils could be observed. They confirmed that the structure of the various layers in the cell wall is substantially the same as had been suggested by previous X-ray and polarization microscope results; in particular, the basic structure of the outer layer of the secondary wall is a flat spiral, although microfibrils running at a steeper pitch are also present. Somewhat similar results were obtained by H. W. Emerton (Kenley), who is concerned with the outer layers of the cell wall because of their importance in connexion with paper-making. In his striking pictures of softwood tracheids obtained with the reflexion microscope, however, he observed only the macrofibrils, and this provoked a discussion as to why his severely treated beaten fibres should show such remarkable macrofibrils, whereas the (presumably) more gently treated material of Frei and Preston should give remarkably clear microfibrils. There is a curious antiparallel here with the results previously mentioned for keratin, where disintegration was claimed to lead to microfibrils and sectioning to macrofibrils. To make matters more obscure, S. Asunmaa (Stockholm) showed sections of laboratory pulps impregnated with heavy-metal atoms, in which little in the way of a fibrillar structure could be seen at all. Some of her preparations did reveal a striated structure, and there were differences attributable to the effects of various chemical treatments.

R. H. Marchessault (Marcus Hook, U.S.A.) and B. G. Rånby (Upsala) have extended the work on the hydrocelluloses produced by the action of mineral acids on cotton and wood, which reduce the microfibrils to elongated rod-like particles, and attempted to correlate the lengths of the particles with the degree of polymerization (osmotic value). A problem which they had to solve was to produce well-dispersed samples; they found sulphuric acid preferable to hydrochloric acid as a hydrolysing agent, while the concentrated acid, low-temperature technique of Mukherjee and Woods[3] gave better dispersions than the dilute acid, high-temperature process of Rånby and Ribi[4]. Sulphation of the surface layers of the particles was suggested as a reason for this.

A long paper on the fine structure of viscose rayon was presented by P. Kassenbeck (Paris). Among other topics, he considered the possibility of obtaining crimped fibres by bilateral heterogeneity, the influence of spinning conditions on the fine structure, and the question of a surface skin on the fibres. He suggested that the skin usually observed in the light microscope is covered by another very thin superficial layer. Can we expect now another battle of nomenclature ?

Much credit for an interesting and stimulating conference is due to Dr. Sikorski, the local organizer.

PHYSICS OF ATMOSPHERIC CLOUDS

DURING January 4–5 the Physical Society and the Royal Meteorological Society held a joint conference on cloud physics in the Department of Meteorology, Imperial College of Science and Technology, London. It was so arranged that on each day four speakers outlined recent developments in a particular branch of the subject ; unusually generous periods were allotted, and needed, for discussion.

On the first day Mr. B. J. Mason (Imperial College) gave a short introductory talk on the scope of the cloud physics to be reviewed, which extended from the laboratory studies of the microphysical processes affecting the formation and growth of cloud particles, to the properties of the extensive cloud systems responsible for cyclonic rains. He was followed by Dr. C. Junge (United States), who spoke on the nuclei of atmospheric condensation, a subject on which much of our present knowledge is due to Dr. Junge's own researches, mostly made since the Second World War, first in Germany and more recently in the United States. He described how the composition and size distribution of the particles of atmospheric aerosol have been investigated, over the enormous range of sizes from a radius of about 10^{-7} cm. to about 10^{-3} cm. The smaller of these particles are the most numerous, usually occurring in concentrations of about 10^4/cm.^{3}, and are those predominantly precipitated in conventional nucleus counters (the 'Aitken nuclei'). Particles with diameters exceeding about 10^{-5} cm. are usually found in size distributions characterized by the relation $dn/d(\log r) = \text{const.}/r^3$, where dn is the concentration of particles in the range of radius dr. The largest particles, the giant nuclei, with radius exceeding 10^{-4} cm., occur in concentrations of less than 1/cm.^{3}, but are important in cloud formation, for they produce a small proportion of unusually large cloud droplets which may readily grow to raindrops by settling through and sweeping up the remainder (the 'coalescence process' of rain formation). The giant nuclei are composed mainly of sea-salt derived from sea-spray, and have been extensively sampled by Dr. A. H. Woodcock (United States) and Dr. H. Dessens (France), who also took part in the conference. Dr. Junge discussed the composition of the somewhat smaller nuclei, which produce the bulk of cloud droplets, and showed that the important constituents are ammonium and sulphate radicals. He particularly emphasized the importance of generating processes and of coagulation and precipitation processes in maintaining the characteristic size-distributions, and the need for more study of the trace materials present in the air in similar concentrations, but in the gas phase. The discussion became a debate on the proportions of cloud droplet nuclei which are produced by sea spray ; the general opinion was that it is their size, rather than number, which makes the sea salt nuclei important.

Dr. H. Weickmann (United States) reviewed information on the constitution of non-precipitating clouds, dividing them for this purpose into stratified and convective clouds. He gave special attention to the relations between the droplet size distribution, the total concentration of condensed water, and the visibility in clouds. He mentioned that the local conversion of supercooled clouds into crystal clouds by seeding is useful as a kind of marking which gives insight into ordinarily invisible turbulent and other air motions in the clouds. Illustrations of the peculiar crystal forms found in ice clouds were drawn from a remarkable series of high-altitude flights in an open-cockpit aircraft which Dr. Weickmann made in Germany during the Second World War. He finally mentioned the iridescent colours, and by inference the droplet constitution, of the rare stratospheric mother-of-pearl clouds, the temperature of which is thought usually to be as low as −80° C. This provoked discussion and alternative inferences from the physicists, who now believe that liquid water freezes spontaneously at about −40° C.

In the afternoon of the first day, Mr. B. J. Mason, speaking rapidly, gave an impressive account of the growth of research upon the nucleation of supercooled water—the initiation and the growth of ice crystals. He discussed the role of homogeneous and heterogeneous nucleation of supercooled droplets, and concluded that in the atmosphere they have predominant importance at temperatures near and below −40° C., and above about −30° C., respectively. He supposed that the effective particles at the higher temperatures are wind-raised silicates. Much more efficient ice nuclei can be made from the iodides of lead and silver, whereas practically all other chemicals can be shown to be inactive. Mr. Mason then reviewed the growth of ice crystals by condensation, and remarked especially that the preferred habit changes with temperature : down to −4° C. hexagonal plates predominate ; between −4° C. and −8° C., and below about −20° C., prisms occur ; while between about −8° C. and −20° C. plates and stars are found. In the laboratory, crystals of startling shape have been grown by varying the temperature : for example, long prisms have been made to sprout upwards from the corners of a hexagonal plate. In the discussion, some speakers challenged the view that only the temperature controls these changes in crystal habit, and Prof. J. D. Bernal doubted if they could be explained by considering only equilibrium states. Dr. Dessens mentioned a small sausage-shaped (presumably organic) type of particle which has been identified as an active ice nucleus in the atmosphere at temperatures below −12° C. Mr. J. S. Turner (Australia) announced a recent experiment which shows that the loss of nucleating activity to which silver iodide smokes are subject in the daylight does not occur at night.

Dr. R. Braham (United States) reviewed the physics of precipitation mechanisms, and emphasized the lack of knowledge of the processes of collision and coalescence between small droplets, which hinders correct appreciation of the importance of the coalescence mechanism of rain formation. He showed that showers form purely by this mechanism in the Caribbean, and that the mechanism still operates in the larger clouds of the eastern United States, whereas the Bergeron–Findeisen ice-crystal mechanism might be the more important in the arid south-western States. These challenging statements and striking flight-observations provoked a lively discussion.

On the second day, Mr. F. H. Ludlam (Imperial College) pointed out that the partitioning (into micro-, macro- and synoptic-physics) of cloud studies, though convenient, must not be made too rigid. It is particularly important that meteorologists (especially dynamicists) should develop the difficult studies of individual clouds, in order that the meteorological conditions within which the microphysical processes operate should be better understood. He illustrated the links which must be sought between the main divisions of the subject by describing some features of convection clouds in the lower troposphere (cumulus), the upper troposphere (cirrus), and the stratosphere (noctilucent clouds). It has been found in Sweden that showers form in cumulus if their tops exceed a rather well-defined level which varies from day to day, and at which the temperature varies from −4° C. to about −25° C. It seems that the coalescence mechanism is responsible for both the shower formation and the extensive production of crystals in the cloud tops. Studies of the other clouds show that there must be a source of atmospheric nuclei, not only at the Earth's surface, but also in the high atmosphere. Examinations of the outer solar corona and the zodiacal light support the hypothesis that cosmic dust settles into the atmosphere at a rate sufficient to provide practically all the nuclei present in the upper troposphere, and to provide concentrations of about 100/cm.^{3} of Aitken nuclei near the ground. The implications of such a universal pollution of practically invisible particles (diameter about 10^{-5} cm.) need careful consideration.

Mr. J. S. Sawyer (Meteorological Office) discussed the properties of the great layer-cloud systems which are associated with cyclones and fronts. The computations of the vertical motion in these atmospheric disturbances, which can now be made with the help of machines, are incapable of resolving internal details that can be deduced from rainfall records and flight investigations. Probably the formation of these cloud systems plays a significant part in cyclone development, for their presence reduces certain braking-effects due to the stable stratification of the atmosphere. Mr. Sawyer described new models of the vertical structure of frontal clouds, based mainly on observations of the Meteorological Research Flight.

On the final afternoon Prof. J. S. Marshall (McGill University) spoke on radar studies of clouds and precipitation. He described the use of millimetre radar, which can 'see' a high proportion of non-precipitating clouds, and of centimetre radar to obtain a three-dimensional representation of snow streamers, which are a characteristic feature of about half of the winter snowfall in Canada. These streamers fall from self-propagating convective cells. He also reviewed new information on the formation of 'bright-band' precipitation echoes, radar evidence of the importance of the coalescence mechanism in shower formation, radar 'angels' at a sea-breeze front, the peculiar hook-shaped echoes associated with tornados, and the spiral-band echoes received from tropical cyclones.

The last contribution was from Dr. T. W. Wormell (Cambridge) on the generation of electricity by thunderstorms. He summarized existing evidence on the distribution of electricity in thunderclouds, and on the rate of charge re-separation in the intervals between lightning discharges. After outlining the classical and more recent theories of charge generation, he remarked that strong electrical activity is found only in clouds containing ice particles. The most recent theory of charge generation, due to Reynolds in New Mexico, attributes it to collisions occurring between ice crystals and small hailstones which are growing by sweeping up supercooled droplets, and which have a surface temperature a degree or two higher than the crystals owing to the release of the latent heat of fusion. This promising theory is now being developed quantitatively; but it is likely to have competition, for a new paper is expected from C. T. R. Wilson, and a proposal by Vonnegut that the large cumulus is for macrophysical reasons an influence machine is attracting attention.

The conference was notable for the very substantial participation of overseas physicists and meteorologists, and for the enormous range of the topics raised. The expansion of cloud physics has been so great that it is now impossible to describe the progress of research other than cursorily in a two-day meeting, even if no reference is made to the possibilities of weather modification which have been such a strong spur to recent work. It was unfortunate that a smog reduced the attendance of the conference; but the audience each day exceeded one hundred and fifty, and its members must have been impressed with the present scope of the subject and the vigour with which its many problems are being attacked.

F. H. LUDLAM

BRITISH COUNCIL

TWENTY-FIRST ANNIVERSARY REPORT

THE twenty-first anniversary report of the British Council*, which includes a congratulatory message and a tribute to the services of the Council from the Prime Minister, covers the year 1954–55 and is unusually brief. Acceptance of the broad principles of the Drogheda Report was only announced by the Government in December 1954, but the effect of the new policy, which included the devotion of £100,000 to the expansion of the Overseas Information Service (including the Council) in 1954–55 and again in 1955–56, has already been felt. For the first time in seven years the Council's grant-in-aid was not reduced, and negotiations were commenced with the Treasury for the establishment of an amalgamated Council service, for the improvement of conditions of service, and for the introduction of a satisfactory pensions scheme. The Council's work and establishment in several Western European countries were reduced, and the small cultural establishment in Germany was disbanded; university teachers were supplied to the Universities of Berlin (Technical University), Göttingen, Hamburg and Mainz. Additional allocations were made for the cultural activities of the

* Report on the Work of the British Council, 1934–1955. Pp. vi + 121 + 6 plates. (Twenty-First Anniversary Report.) (London: British Council, 1955.) 2s. 6d.

Brussels Treaty Organization (Western European Union and the Council of Europe). The Council's representation in New Zealand was withdrawn, and its establishments in Australia and Ceylon were closed; but work in Persia was resumed.

The number of students who were met on their first arrival from overseas reached the record total of 4,164, 3,771 being Colonial students, while new and better premises for this work among students were acquired in Aberdeen, Belfast, Edinburgh and Oxford. Two awards were made to university professors for short visits to the United Kingdom, and seven for visits to other Commonwealth countries, while forty-two travel grants were made to university teachers or postgraduate workers for study visits to the United Kingdom, ten for study visits from the United Kingdom and two for study visits between overseas countries. There were also forty-nine short visits to the United Kingdom universities and forty-nine visits to foreign universities. Some twenty-nine lecture tours and advisory visits overseas were arranged in science, medicine, agriculture and engineering, and twenty-one in education, sociology, philosophy and law; besides tours and exhibitions, the Council supplied about 82,000 books to Council and Council-associated libraries and secured 6,921 reviews of British books in overseas periodicals. Of the lecture tours arranged, 33 per cent were in medicine and science, and 25 per cent in education, while of the 1,488 film prints distributed in fifty-five countries, 216 were medical and 220 scientific and technical.

Most of the report is occupied by a historical review by Sir Harold Nicholson of the inception of the Council and the development of its work from 1934 to 1955, including a critical appreciation of that work. This is followed by an appreciation of its present activities by the new director-general, Sir Paul Sinker, and there is also an appreciation of Sir Ronald Adam's work by Sir Philip Morris. Since the end of the Second World War the Council has arranged programmes for 35,726 overseas visitors, mainly professional people or technicians, including many who have come under United Nations or Colombo Plan programmes; but the proportion of such visits financed wholly or in part by the Council has fallen from 66 per cent in 1945–46 to 16 per cent in 1954–55.

LONG ASHTON RESEARCH STATION

REPORT FOR 1954

A CONSIDERABLE number of papers on various aspects of disease control is to be found in the report for 1954 of the Agricultural and Horticultural Research Station, Long Ashton, Bristol, which has recently been published*. Such a concentration in no way disturbs the general efficacy and breadth of the report, as it relates to other aspects of fruit culture and fruit products. It serves, rather, to integrate the results of several workers, thus giving a special, as well as a general, significance to an annual report of progress.

On the question of materials for disease control, G. V. Coles, J. T. Martin and R. J. W. Byrde have investigated the fungicidal properties of coal-tar distillates against *Ceratostomella fimbriata*, causing mouldy rot of newly tapped bark of the rubber tree. The predominating effect of the phenol fraction in determining fungicidal efficiency was confirmed by chemical analysis and bioassay. R. J. W. Byrde and A. T. K. Corke found that sporulation of *Nectria galligena* on apple cankers was reduced for about eighteen months, following treatment with 0·3 per cent phenyl mercury chloride. Burgundy mixture has been used for a long period of years, but E. Somers has demonstrated that the mixture 10 lb. copper sulphate, 14 lb. sodium carbonate, 100 gall. water, gives the best tenacity on potato foliage, when applied against blight. Post-dormant sprays of DDT and BHC kill some predators of the red spider mite; H. G. H. Kearns, N. G. Morgan and A. H. Wilkins have found that eggs of the mite can be controlled effectively by spraying with 0·05 or 0·02 per cent chlorbenside (*p*-chlorbenzyl *p*-chlorphenyl sulphide). Applications were made at the pink-bud stage of Worcester Pearmain apples, and were not effective at earlier stages.

Specifications for two light-weight small-power sprayers are given by H. G. H. Kearns and N. G. Morgan. They use 34-c.c. and 70-c.c. petrol engines, and deliver 8 and 19 pints/min., respectively, both at 75 lb./sq. in. There is considerable interest in the relative efficacy and operational economy of small-volume air-flow spraying. Messrs. Kearns and Morgan have also found the method effective against potato blight, but the same authors, with R. W. Marsh, record that apple scab control using lime sulphur or captan required more air-flow applications to be as effective as large-volume spraying. Small-volume sprayings accentuate the need for studies on spray-droplet size and distribution. C. G. L. Furmidge has two papers on this question; one of them describes field methods in which droplets are estimated as impressions in magnesium oxide, or as stains on glass, plaster of paris or various paper surfaces. Methods for the assay of captan deposits are described by J. T. Martin and J. A. Pickard, while the distribution of copper and DDT deposits are discussed in relation to the method of application by N. G. Morgan and J. T. Martin. Finally, R. W. Marsh considers results on apple scab control over eleven years with a view to the formulation of a modern spray policy for the fruit grower. Results from 1954 are marshalled to the same end by R. J. W. Byrde, G. M. Clarke and C. W. Harper. The general conclusion from both these papers appears to be that captan and phenyl mercury chloride, among the newer fungicides, are most likely to find places in the normal spray schedule for apple varieties which are 'russeted' by lime sulphur.

The mycological side of plant pathology is represented by a paper by A. T. K. Corke, who finds that inoculations with mycelium of the bitter rot fungus *Gloeosporium perennans* on apple branches produced cankers at all times of the year. Inoculations with spore suspensions, however, were generally successful only in November and December. From the section of pomology, R. R. Williams, continuing an earlier study, has described a further eleven varieties of perry pears from Herefordshire and Gloucestershire. The same author has a final report on yields and orchard behaviour of thirty-two varieties of cider apples grown as bush trees during 1950–53, and pollen requirements of these particular apples have been studied. A. I. Campbell has found that Brompton and Common Mussel plum stocks are suitable for the four new plum varieties Teme Cross, Severn Cross, Frome Cross and Thames Cross, all raised at Long Ashton. A report by D. L. Abbott shows that 2 : 4 : 5-TP at 40 p.p.m. was effective as a fruit-ripening agent on Worcester Pearmain apple when sprayed on the leaves rather than on the fruit. Barbara A. Rake has studied the influence of basal wounding and size of shoot on the rooting of hardwood cuttings of the gooseberry.

---

* University of Bristol. The Annual Report of the Agricultural and Horticultural Research Station (The National Fruit and Cider Institute), Long Ashton, Bristol, 1954. Pp. 207+13 plates. (Long Ashton: The Station, 1955.) 15s.

Two crop failures on acid soils are described in the section on plant nutrition. One (by C. Bould and E. G. Bradfield) was of apples, in soil of pH 3·9–4·2, and the other (by W. Plant, of the Agricultural Research Council Unit of Plant Nutrition) was of carrots at pH 4·5.

The vintage quality of cider produced from bush trees has been evaluated by L. F. Burroughs. Many samples were of excellent quality, but the locality at which the fruit was grown influenced the composition of the juice and the vintage quality. F. W. Beech describes two methods of producing bottled cider free from deposit, either by sterile filtration before bottling or pasteurization after bottling. Alice Crang and Margaret Sturdy present continuing progress reports on the preservation of vegetable varieties by canning and freezing, and on fruit varieties by bottling and freezing.

The annual report is produced to the usual high standards of printing and illustration, and as a final instance of its comprehensiveness, there is a paper on statistics by G. M. Clarke and A. T. K. Corke. This considers sources of variability in sampling black currants for leaf-spot. It leads to the conclusion that a redeployment of available labour would have brought greater precision if more bushes had been sampled with fewer shoots per bush. This is a good example of the team work and integration which are evident from all the work of the Station.

JOHN GRAINGER

RELATIONSHIP BETWEEN LENGTH OF DAY AND GEOTROPIC RESPONSE IN SEEDLINGS

By E. DOROTHY BRAIN

SENSITIVITY and response to gravity in fern fronds[1] and various species of seedling[2] have been shown to be influenced by the stage in development rather than the size or growth-rate of the plant organ. Sensitivity to light has also been found to vary with the age and stage of development of the seedling of *Avena* at the time of illumination[3]. It is therefore significant that seasonal variation in response to gravity which has been recorded for *Lupinus polyphyllus* seedlings[4,5] can be correlated both with the rate of development of the seedling and the distribution of statolith starch in the developing plant. Experiments have shown that both response to gravity and efficiency of the statolith apparatus decreased in the winter months in plants grown entirely in the dark and under normal conditions. If the plants were given longer daily periods of light in the winter by illumination with a 25-watt 'Mazda' electric bulb, their rate of development was increased and they became more reactive in response to gravity in the later stage of the seedlings' development, when response in control plants was falling off. The pattern of their geotropic response became similar to that for the summer when activity is at its optimum. In summer, when the day was lengthened by giving 2 or 2·5 hr. extra light artificially, the response to gravity was raised above that of the controls, and with 4 hr. extra light the increased response was more marked. Comparisons were based on the percentage of plants in a series which responded to a stimulus (that is, period of horizontality) of 20 min., which was known to be the presentation time for the *Lupinus polyphyllus* seedling.

An examination of the distribution of statolith tissue, at different times of year, in seedlings grown in the dark and in the light, has shown a similar variation. There was found to be an optimum condition of the statolith apparatus in seedlings for the summer which corresponded with the optimum for geotropic activity in the later stage of development when the cotyledons were opening and the epicotyl beginning to develop.

An examination of the statolith distribution at this stage has also been made in seedlings which were given extra light in the winter and summer months. The methods used were the same as those described in a recent publication, and the seedlings were classified into the following groups according to: (*a*) The extent of statolith tissue in the hypocotyl: (1) from the cotyledonary node to the collet; (2) from the cotyledonary node half-way down to the collet; (3) at the apex or in the cotyledonary petioles; (4) having no statoliths. (*b*) The number of statoliths seen in transverse section at the upper part of the

Table 1. PERCENTAGE OF PLANTS

		No. of plants	Extent of statolith tissue (1)	(2)	(3)	(4)	Number of statoliths (1)	(2)	Size of statoliths (1)	(2)
Nov.	Control	17	23 52	52·94	23 52	0·0	70 58	29 41	47·04	52 94
,,	6·5 hr. extra light	6	83 33	16 66	0·0	0·0	50 0	50·0	50·0	50 0
Jan.	Control	15	13·33	13 33	66·66	6 66	60·0	33·33	46·66	46·66
,,	6·5 hr. extra light	15	26 66	26 66	40·0	6·66	46·66	46 66	20·0	73·3
June	Control	3	100·0	0 0	0 0	0 0	100·0	0·0	100·0	0·0
,,	2·5 hr. extra light	4	100·0	0 0	0·0	0 0	100·0	0 0	75·0	0·0
,,	4·0 hr extra light	4	100·0	0 0	0 0	0·0	100·0	0·0	75·0	0 0

hypocotyl: (1) more than four; (2) less than four. (c) The size of the individual statoliths in statocytes at the upper part of the hypocotyl: (1) diameter 4·9μ; (2) diameter 2·5μ or less. The numbers found in each group were compared as percentages of the series and the results are shown in Table 1.

It will be seen that plants given extra light in the winter had a higher percentage with the maximum amount of statolith tissue than controls. In June no effect of extra light was shown on the extent of statolith tissue; but in January and June there was a tendency for the statoliths to be smaller in plants which had received extra light. A quantitative examination of the statolith apparatus* in some fifteen species of seedlings made by Hawker[2] demonstrated a very close correlation between the volume of statolith tissue and the degree of sensitivity to gravity. Seasonal variation in geotropism in *Lupinus polyphyllus* gives another example of this. In winter, when development is slow, geotropic response and the amount of statolith tissue declines before the epicotyl develops. By increasing the period of light received daily the epicotyl development is hastened and geotropic response and statolith efficiency are also increased. In summer, when normally development and geotropic response are at their maximum, extra light raises the response to gravity in the later stage of development.

It therefore seems evident that it is the effect of light on the rate of development of the seedling which is the factor responsible for the changes in geotropic response which have been observed.

SPONTANEOUS CHROMOSOME BREAKAGE IN ENDOSPERM

By Dr. A. RUTISHAUSER
University of Zurich
AND
L. F. La COUR
John Innes Horticultural Institution, Bayfordbury, Hertford, Herts

Recent studies have shown that endosperm nuclei may show a higher incidence of spontaneous chromosome breakage than those in any other plant tissue. A possible exception is the nuclei in the tapetum, where conditions are not particularly favourable for study. Its incidence in endosperm nuclei seems to be related to special genetic and hybrid conditions. For example, mass chromosome breakage was found in endosperms of a lily hybrid, and similarly a high degree of breakage was observed in endosperms obtained from self- and cross-pollinations of *Ranunculus auricomus*[1].

It was concluded by Brock[2], from a study of endosperms obtained from crosses between hyacinth varieties, that chromosome balance had a marked effect on breakage conditions. He found breakage was slight in endosperms from diploid–diploid crosses, but became progressively greater in endosperms from diploid–trisomic and diploid–triploid crosses.

The present investigation is largely concerned with an attempt to evaluate the effect of hybridity involving nuclear and cytoplasmic interaction on chromosome behaviour in endosperm tissue. To obtain this we have used endosperms from intergeneric fertilizations using *Paris quadrifolia* $2n = 20$, *Trillium cernuum* and *T. grandiflorum*, both $2n = 10$. This material is particularly favourable since in the hybrid endosperms we can readily distinguish at least four of the five *Trillium* chromosome types from the chromosomes of *Paris* by a difference in heterochromatin content (Fig. 1). With cold treatment only the *Trillium* chromosomes show weakly-staining and therefore readily distinguishable blocks of heterochromatin (Fig. 2)[3]. In *T. grandiflorum* it is sometimes the *A*- and in *T. cernuum* the *C*-chromosome which shows no such distinguishing feature.

To reveal the heterochromatic segments, plants with developing seed pods received a four to five day treatment at just above 0° C. prior to fixation and preparation of the endosperm for chromosome studies[4]. Because of slow development, cold treatment was not given until twenty to forty days after pollinations were made.

Spontaneous chromosome breakage was found in endosperms from all three kinds of crosses made. It was high in endosperms of *Paris* ovules fertilized with *Trillium* pollen, and low in the reciprocal cross *T. grandiflorum* × *Paris*. Ovule development was poor

* The unequal frequency of chromosome types is mainly due to chromosome loss.
† The *C*-chromosome is not readily distinguishable.

in this latter cross, but sufficient endosperms were examined to show that the difference in breakage, which is of an order of about 20 : 1, is a valid one (Table 1).

It can be noted that the low frequency of breakage in *Trillium–Paris* crosses is not significantly higher than that in endosperms obtained from *Trillium–Trillium* crosses (unpublished data from examination of more than two thousand nuclei in fifty crosses).

A particularly interesting feature was that breakage is confined to *Trillium* chromosomes. We must emphasize that none of the broken chromosomes could have been transmitted through the pollen, because many of the hybrid endosperm nuclei contained normal unchanged *Trillium* chromosome sets.

Breakage occurs both in eu- and hetero-chromatic segments. Unfortunately, an exact analysis of initial breakage is not possible, since secondary changes arising from breakage of bridges at anaphase are superimposed on initial breakage, which we believe occurs spasmodically throughout endosperm development in this material. Breakage of chromosomes is followed by reunion to give dicentrics, rings, translocation and sister reunion, all of which occur in our material. Our analysis at metaphase is based on these changes, together with changes disclosed by visible loss or gain of segments. This is made possible by the pattern of eu- and hetero-chromatic segments.

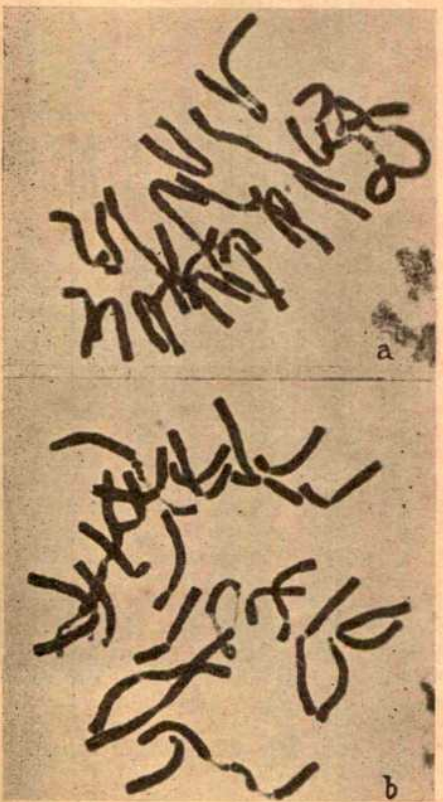

Fig. 1. Microphotographs of metaphases from endosperms of the cross *Paris quadrifolia* × *Trillium cernuum* showing 25 chromosomes. The five *Trillium* chromosomes show heterochromatic segments revealed by cold treatment. In (*a*) a *Trillium* *A*-chromosome shows loss of part of an arm; in (*b*) again loss in an *A*-chromosome together with a dicentric chromosome. × 1,200 *Note.* The embryo-sac development in these species is of the '*Allium* type' and the endosperm nuclei are therefore triploid in constitution. Endosperms from *Paris* × *Trillium* contain 20 *Paris* chromosomes and 5 *Trillium* chromosomes and in the reciprocal cross 10 from each parent

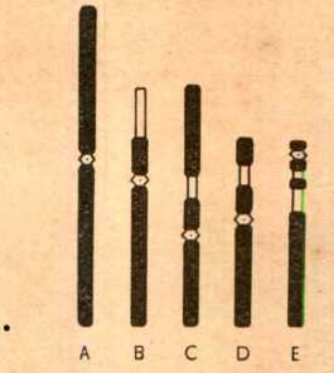

Fig. 2. Diagrammatic illustration of the five chromosome types in *Trillium grandiflorum* showing relative lengths of eu- and hetero-chromatic segments. Heterochromatin in outline, euchromatin in black and centromeres in outline with a dot

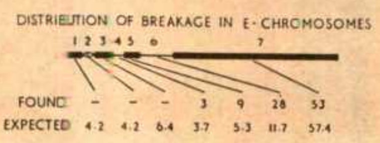
Some interesting features emerge when we study the distribution of breakage between chromosomes and in individual chromosomes. First there is an extremely unequal distribution of breakage between chromosomes. In the crosses between *Paris* and *T. grandiflorum*, most of it occurs in the *E*-chromosomes, and clearly this is not related to chromosome length or heterochromatin content (Fig. 2). Secondly, within the *E*-chromosomes of this cross, we find distribution of breakage is non-random.

If we divide the *E*-chromosome into seven parts, namely, short arm, centromere and eu- and hetero-chromatic segments, we find breakage in the long arm is relatively greater in segments distal to the centromere, and somewhat disproportionate in eu- and hetero-chromatic segments according to length (Fig. 3). Although it is perhaps unwise to speculate unduly on the significance of these observations, nevertheless it is tempting to invoke centromere interference as favouring the distal distribution.



DISTRIBUTION OF BREAKAGE IN E-CHROMOSOMES
1 2 3 4 5 6 7
FOUND – – – 3 9 28 53
EXPECTED 4·2 4·2 6·4 3·7 5·3 11·7 57·4

Fig. 3. Expected values based on a random distribution

It is clear, at least from the *Paris–Trillium* cross, that hybridization can influence the rate of spontaneous chromosome breakage in endosperm nuclei. It might be thought that the difference in response of *Paris* and *Trillium* chromosomes to change of cytoplasm is against the view that the *Paris* cytoplasm plays a predominant part in influencing breakage in *Trillium* chromosomes. Alternatively, we might suppose that the interaction of two genetic systems leads to special conditions favouring the induction of chromosome breakage by changes in cell metabolism. At the moment, because of insufficient evidence, we can make no decision as to which of these views we most favour.

One of us (A. R.) is the recipient of a grant from the Swiss National Fund. [Sept. 23

Dimorphism of Polyglycine

THE two crystallographic forms of polyglycine observed by Meyer and Go[1] have recently been re-investigated by other workers[2-4]. This problem has also been studied in these laboratories.

Polyglycine prepared by the polymerization of diketopiperazine in water at 60°–180° C., or by direct polymerization of glycine at 140° C.[5], shows strong X-ray reflexions at 3·45 A. and 4·4 A.; this is polyglycine I [3]. It is similar to the material obtained by the polymerization of anhydrocarboxyglycine in hot pyridine[1] or in ethyl acetate[2], and its structure, proposed by Astbury[2], resembles that found in the polyamides[6].

If polyglycine I, prepared as in ref. 5, is dissolved in saturated calcium chloride solution and precipitated at 20° C. by the addition of water, the product shows reflexions at 4·15 A. (vs) and 3·1 A. (m); this is polyglycine II [3]. A structure for this material has recently been proposed by Crick and Rich[4], in which the polymer chains are packed hexagonally.

Our preparations of polyglycine II, when examined under the electron microscope, showed crystals almost hexagonal in shape. Slow precipitation of the last, most soluble, portion of our preparation gave hexagonal crystals as in Fig. 1; with lithium bromide[1] the regularity of the crystals was less perfect. The crystals show growth steps, similar to those observed by Dawson and Vand[7] for homogeneous substances, though the formation is less perfect.

The number-average degree of polymerization of our preparation, in bulk, was 12·2, although that of the fraction which gave Fig. 1 may be lower. The expected height of successive steps would be about 40 A. for a degree of polymerization of 12·2; this is somewhat higher than the value estimated from the apparent length of shadows in the electron micrographs. This discrepancy is caused by the necessarily low accuracy of the latter method, and uncertainty as to the actual degree of polymerization of this particular fraction of polymer.

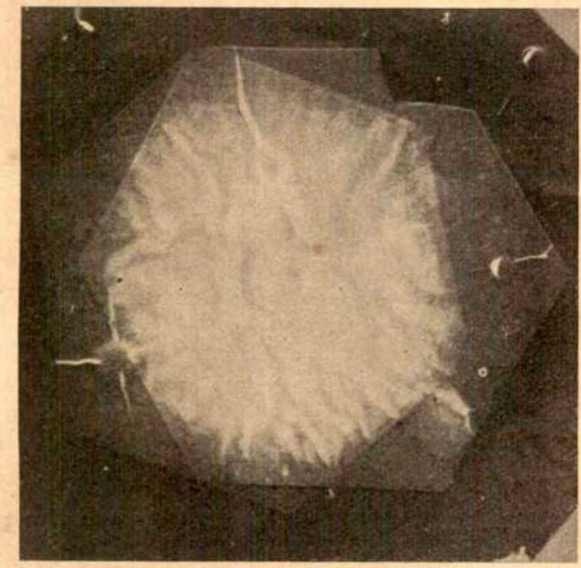

Fig. 1. Polyglycine type II (ref. 3); two overlapping hexagonal crystals. × 6,000

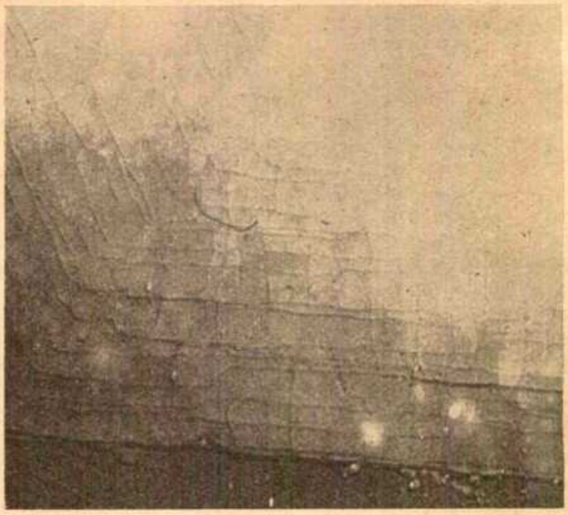

Fig. 2. Same as Fig. 1; details of terrace structure and lattice dislocations. × 30,000

The formation of growth steps in the case of homogeneous materials is due to the occurrence of dislocations in the crystal lattice. The occurrence of dislocations is not surprising in our material, since it is not homogeneous with respect to degree of polymerization. We have, so far, not been able to obtain crystals thin enough to demonstrate, with a sufficient degree of contrast in the photographic reproductions, the details of the dislocations in the centre of the crystals, although the examination of some of our original electron micrographs confirms the appearance of such effects. However, close examination of the fine detail near the edges of crystals in most of our electron micrographs, even at moderate magnifications, shows this effect very clearly (Fig. 2).

Fig. 1 shows two superimposed and relatively thin crystals obtained from the same fraction. The unfractionated polymer, degree of polymerization 12·2, gives crystals which are smaller and more opaque to electrons, that is, thicker. The material in Fig. 1 is probably lower in degree of polymerization and more homogeneous; it seems that this increases the rate of condensation on the edges and reduces it on the face of the crystal.

The transition polyglycine I ⇌ polyglycine II seems to be dependent on temperature. When a solution of polyglycine I in calcium chloride is precipitated at 100° C., polyglycine I is recovered; electron micrographs obtained during preliminary work show flat parallelograms (axial ratio 0·9, acute angle about 70°). At temperatures between 100° C. and 60° C. the product shows an X-ray diffraction pattern intermediate between I and II, with a rather marked change at 60°, below which type II polymer is obtained. On the other hand, if type II polymer is dissolved in calcium chloride solution and precipitated at 100° C., type II polymer is recovered. It seems that there is a tendency for the polymer to be precipitated in the form in which it went into solution, presumably due to the persistence of crystal nuclei. If type II polymer is heated to 140° C. in water, it is partially converted into type I. We believe that polyglycine has a transition temperature in the region of 60° C. The type II polymer obtained at 100° C. was probably a metastable preparation.

The importance of the thermal equilibrium in the mechanism of the formation of dislocations has been stressed by Frank[8], and we believe that further work on such effects may prove to be of great value in the studies of protein denaturation.

The density of polyglycine was determined with a specific gravity bottle at 22·5° C. and 65 per cent relative humidity, using toluene as displaced liquid.

Polyglycine (type)	I	II	I
Degree of polymerization (number average)	8·4	10·6	12·2
Density (gm./c.c.)	1·469	1·475	1·486

Thus there is an increase in the density with increasing value of the degree of polymerization. The structure of polyglycine I requires a density of 1·56 gm./c.c.[2], and the structure proposed by Crick and Rich[4] for polyglycine II 1·54 gm./c.c.

Temperature Effects in the Paper Partition Chromatography of Sugars

The maintenance of a constant and uniform temperature within the apparatus is universally recognized as an essential for the production of satisfactory paper partition chromatograms. The effect of the temperature at which the chromatograms are made has, however, been comparatively little studied.

Consden, Gordon and Martin[1] reported variations in the R_F values of amino-acids chromatographed over the temperature-range 7–25° C. Hough, Jones and Wadman[2], who chromatographed sugars at 20° C. and 37° C., reported that at the higher temperature there was faster movement, improved definition of the spots and higher R_F values. Counsell, Hough and Wadman[3] also showed that in the chromatography of sugars the R_F values were influenced by the temperature of working, and that somewhat larger quantities of material could be handled at higher temperatures. They also stressed the importance of maintaining the whole apparatus at a constant temperature and of ensuring adequate equilibration within the apparatus before starting the chromatogram. These conditions may be difficult to fulfil using a large conventional tank, and we have described elsewhere[4] a small all-metal apparatus designed to facilitate working at temperatures other than that of the laboratory. Using this apparatus we have been able to compare the R_F values of a number of sugars throughout the temperature range 0–50° C.

This series of experiments showed that R_F values of sugars vary considerably with temperature and it became apparent that, as in the case of the amino-acids reported by Consden, Gordon and Martin, the factor exerting the greatest influence was the water-content of the solvent. In the case of solvents having an increased water content at higher temperatures the R_F values increased over the range 0–50° C. The opposite effect was shown by solvents having a negative temperature coefficient with respect to water content, that is, the R_F values decreased over the range 0–50° C. Since they are so greatly influenced by the temperature of working, it follows that when R_F values are quoted the temperature at which the separations were made should be specified.

Isherwood and Jermyn[5] have related the R_F values of any individual sugar in a series of different solvents to the molar fraction of water present in each solvent. They obtained a straight line on plotting log $(1/R_F - 1)$ against $-\log N$ (where N is the molar fraction of water in the moving phase). Apart from R_F, N is the only variable in this equation, which should, therefore, be applicable to the changes in R_F produced by using the same solvent at different temperatures, if these variations are dependent on the water content of the solvent. Plotting log $(1/R_F - 1)$ against $-\log N$ for our data, using values for N calculated from data given in the International Critical Tables, a straight line is obtained. Some examples are shown in Fig. 1. Thus we have been able to confirm the Isherwood and Jermyn relationship and to show that the effects of temperature on the R_F values are the result of the variations in the solubility of water in the moving phase.

Changes in temperature also influence the speed of development of the chromatogram since the

physical characteristics—density, viscosity and surface tension—of the solvent are affected and hence the 'diffusion coefficient' of the paper. Müller and Clegg[6] have investigated the rate of the movement of the solvent along the paper. They conclude that the distance moved by the solvent front is in accordance with the equation

$$h^2 = Dt - b$$

where h is distance moved by the solvent front, D is diffusion coefficient, t is time, b is a constant. The diffusion coefficient can be expressed in terms of the physical constants of the solvent by using the relationship

$$D = a\gamma/\eta d + b$$

where γ is surface tension, η is viscosity, d is density and a and b are constants for the paper.

Thus temperature effects on the diffusion coefficient and hence on the distance moved by the solvent front in a given time can be predicted from a knowledge of the temperature coefficient of the ratio $\gamma/\eta d$. The physical data available are unfortunately insufficient to allow of a quantitative treatment.

All separations were carried out on strips of Whatman No. 1 filter paper six inches wide and cut across the machine direction of the paper. Five standard solutions each containing three different sugars were prepared, and aliquot portions were applied to the paper in the usual way. Thus, fifteen sugars could be compared on one paper. After application of the spots the apparatus was set aside for a minimum of four hours to allow the paper, the atmosphere and the solvents to reach a state of equilibrium. In order to reduce the number of variables to a minimum, only two-component solvent systems were investigated. In every case the phases were allowed to equilibrate at the temperature at which the chromatogram was to be made before the organic phase was introduced into the apparatus. Table 1 gives the results at four different temperatures for three typical sugars—melezitose, glucose and rhamnose—with a number of different solvents. Fig. 2 illustrates the relation between R_F values and temperatures for a series of sugars chromatographed with water-saturated butanol. Since solvents having a decreased water content at higher temperatures are much the rarer kind, R_F values for this type can be given only for *s*-collidine. Experiments with triethylamine, however, have shown the same general tendency, although the extreme volatility of this solvent makes it impossible to give accurate results.

Bacterial Degradation of Nicotinic Acid

A BACTERIUM utilizing nicotinic acid was isolated from culture media made up of a solution of nicotinic acid and dilute sodium sulphide and inoculated with a small amount of Potomac mud. After allowing the bacteria to grow anaerobically, several successive transfers were made into a medium containing nicotinic acid, peptone, yeast extract, metals, phosphate and sodium sulphide. The mixed bacterial suspension was then serially diluted in agar media of the same composition under anaerobic conditions. This serial dilution was repeated until the bacterium utilizing nicotinic acid was isolated in pure culture. By this enrichment culture technique, an anaerobic spore-forming rod was isolated which ferments nicotinic acid and which utilizes high concentrations of this compound for its growth. Maximum growth is achieved in the presence of 0·6 per cent yeast extract, 0·2 per cent peptone and 0·4 per cent nicotinic acid. No growth occurs with yeast extract and peptone alone. Neither will the bacterium grow on nicotinic acid as a sole source of carbon.

In growing cultures of this organism, it was observed that acetic and propionic acids were formed from nicotinic acid. These acids were determined by paper chromatography[1] and also separated on a silica-gel column[2]. They were present in equal amounts. Further studies with resting cell suspensions demonstrate that nicotinic acid was fermented to ammonia, carbon dioxide, acetic and propionic acids according to the following reaction:

$$4H_2O + C_5H_4N\text{—}COOH \rightarrow NH_3 + CO_2 + CH_3COOH + CH_3CH_2COOH$$

TABLE 1

Additions: 20 mgm. washed cell suspension, 200 µmoles phosphate buffer *p*H 6·0, nicotinic acid as indicated, water to 2 ml. final volume. Gas, nitrogen. Temperature, 26° C. Reaction started with the tipping of the bacteria and continued to cessation of gas production. Figures corrected for endogenous metabolism

Nicotinic acid added (µmoles)	0·94	1·89	3·76
Carbon dioxide produced (µmoles)	0·82	1·65	3·25

TABLE 2

Additions: 20 mgm. washed cell suspension, 50 µmoles potassium bicarbonate, nicotinic acid as indicated, water to 2 ml. final volume. Gas, 5 per cent carbon dioxide in nitrogen. Temperature, 26° C. Experiment started with the tipping of the bacteria and continued to cessation of gas production. Figures corrected for endogenous metabolism

Nicotinic acid added (µmoles)	0·94	1·89	3·76	5·65	7·5
Acid produced (µmoles carbon dioxide)	0·94	1·88	3·20	4·70	6·15

Table 1 demonstrates that resting cells will catalyse the formation of carbon dioxide from nicotinic acid. In Table 2 it can be seen that for each mole of nicotinic acid in the reaction mixture approximately one mole of acid was produced as measured by the release of carbon dioxide from bicarbonate buffer at *p*H 7·4. Since three acids and one base are produced from one acid by this reaction, only one acid equivalent can be measured by this technique.

In a typical large-scale experiment, 131 µmoles of nicotinic acid were incubated in bicarbonate buffer at *p*H 7·4 with a suspension of resting cells until acid production ceased. All the nicotinic acid, as determined by the cyanogen bromide method[3], had disappeared. As measured by release of carbon dioxide from the bicarbonate buffer, 109 µmoles of acid, corrected for endogenous acid production, were formed. 122 µmoles of ammonia was also formed.

The reaction mixture was then acidified and steam distilled, and 345 µmoles of steam-volatile acids collected. This was shown to be, by paper chromatography, a mixture of acetic and propionic acids. A comparable cell suspension incubated without nicotinic acid produced 128 µmoles of acetic acid and no propionic acid. Thus, correcting for this endogenous production of acetic acid, 217 µmoles of acetic and propionic acids was produced from nicotinic acid. Determination of the Duclaux numbers of this mixture demonstrated that, of the total acid produced from nicotinic acid, 110 µmoles was acetic acid and 107 µmoles was propionic.

The acid mixture was separated on a silica gel column into acetic and propionic acids. These were identified by their positions on silica-gel columns and paper chromatograms, and by Duclaux distillation. Acetic acid was also characterized as the sodium uranyl acetate[4].

I wish to thank Dr. E. R. Stadtman for helpful discussions during the course of this work.

Preparation of Antiglobulin Sera

THE antiglobulin test of Coombs, Mourant and Race is already widely employed in routine practice, and many laboratories are producing for themselves antiglobulin sera. Rabbits were commonly immunized by unchanged human serum or its globulin fraction. The latter method, especially in the smaller laboratories, meets difficulties.

The technique employed by us is very simple. To 1 ml. of packed rabbit red cells are added 10 ml. of pooled human serum heated for 30 min. at 56° C. The tubes are then left in room temperature for 30 min., being shaken several times. The agglutinated cells are washed three times with saline, suspended in 3 ml. of saline and injected into the ear vein. For immunization two injections weekly were carried out for six weeks. For each injection freshly prepared agglutinate was used. The rabbits did not show any abnormal symptoms.

By this method four antiglobulin sera were obtained, and they have been used for the past six months in routine tests of our laboratory. All the antiglobulin sera have sufficiently high titres; human red cells sensitized by incomplete anti-*D* sera were agglutinated by two antiglobulin sera up to the dilution of 1 : 1,280; the titres of the remaining two sera were 1 : 5,120 and 1 : 20,480 respectively. The injections caused no increase in the titre of natural heteroagglutinin against human red cells, and the titre of this antibody remained low, that is, about 1 : 4. Our antiglobulin sera could be therefore employed (without previous absorption) at several dilutions, and errors caused by zonal phenomena could be eliminated.

Antiglobulin sera obtained by our technique contain antibodies against globulin denatured on the surface of red cells as a result of antigen–antibody reaction. In this connexion one would expect greater specificity of the tests performed with our sera than with sera obtained otherwise.

Metabolism of Sorbitol

WE have recently investigated the metabolism in man of sorbitol uniformly labelled with carbon-14. The results show clearly that sorbitol is rapidly and relatively completely metabolized to carbon dioxide in the normal and in the diabetic subject. Table 1 shows that, after an oral dose of 35 gm. of sorbitol containing carbon-14 sorbitol (total activity 30 µc.), the expired carbon dioxide became highly radioactive within an hour and remained active for a further 8 hr. Only about 10 per cent of the activity appeared in urine and fæces. The exact percentage of recovery of radioactive carbon in the expired carbon dioxide cannot be calculated in these two cases without certain assumptions regarding the total

Table 1. Activity of Expired Carbon Dioxide after the Ingestion of 35 gm. of Sorbitol uniformly labelled with Carbon-14 (total activity 30 μc.)

Normal subject		Diabetic subject	
Time after ingestion of sorbitol (hr.)	Counts/min./gm. carbon dioxide	Time after ingestion of sorbitol (hr.)	Counts/min./gm. carbon dioxide
1	411	½	54
3	820	1	134
4	838	3	519
6	475	4½	750
8	260	5½	670
24	0	7½	456
		10½	260
		24	0

carbon dioxide production, which for experimental reasons could not be measured in these tests. Nevertheless, at least 70 per cent and probably 90 per cent of the activity administered can be acounted for in the expired carbon dioxide.

Our investigations so far throw no light on the pathway of metabolism of sorbitol, but show clearly that this polyhydric alcohol must provide calories. Its precise mechanism of metabolism in both the normal and diabetic subject requires further investigation.

We wish to thank Messrs. Howards of Ilford, Ltd., for financial support of this investigation.

Antenatal Sex Determination

For thousands of years people have had a desire to know the sex of an expected child. Many methods have been tried for antenatal sex determination; but even modern ones, based upon scientific hypotheses, have failed to receive sufficient confirmation for general acceptance.

Since Barr *et al.*[1], in 1949 in *Nature*, described morphological sex differences of the nerve cell nuclei of cats, their observations have been repeated on several human and animal cell types. The observation that the cell nuclei of the amniotic membrane in cats[2] and of the oral epithelium of newborn infants[3,4] exhibit easily demonstrable sex differences led to an investigation whether human amniotic fluid contains enough well-preserved desquamated cells to make possible the determination of the fœtal sex.

Amniotic fluid was collected from pregnant women at term by rupture of the membranes for induction of labour. In a few cases the fluid was obtained in the middle of pregnancy from cases for surgical interruption, by puncture of the membranes through the uterine wall either vaginally or through a laparotomy. Care was taken to avoid admixture of maternal cells. The specimens were centrifuged and the vernix and supernatant fluid removed. The cells were smeared on microscopical slides coated with egg-albumin or human serum and fixed in Papanicolaou's fixative. The staining procedure was carried out with cresyl violet as described by Moore and Barr[4].

The smears were examined by one of us without knowledge of the fœtal sex even in those cases where delivery had taken place before the examination could be carried out. One of our first specimens was misinterpreted owing to lack of experience, but after that our results have been correct in all of twenty cases. Numerous well-preserved cells are found at term, and enough in the middle of pregnancy to allow a definite distinction between male and female cells by the absence or presence of the typical sex chromatin mass in the cell nuclei. Many of the cells have a close resemblance to those of oral smears and might conceivably be epithelial cells from the fœtal alimentary or genito-urinary tracts.

The crucial point of the method is the avoidance of admixture of maternal cells. If the puncture is made through the uterine wall, a needle with a stylet should be used; and if the amniotic fluid is collected by rupture of the membranes from below, a catheter should be inserted into the bag of water. The specimens should be fixed as soon after collection as possible to avoid autolysis.

Although transabdominal puncture of the uterus has been carried out often for therapeutic and experimental reasons without accidents, mere curiosity does not justify the procedure, and its practical value is probably limited in the human. If the results are confirmed in animals, however, it might become of great significance in veterinary practice.

Effect of ββ-Methylethyl Glutarimide and Amytal on Rat-liver Mitochondrial Respiration

In 1954, Shaw *et al.*[1] showed that ββ-methylethyl glutarimide was capable of reducing the narcotic effect of barbiturates in animals and man, and suggested that in therapeutic dosage it exerts a direct antagonism to barbiturates.

It has been known for a long time that barbiturates depress the respiratory system of the cells, and preliminary experiments[2] seem to show that a certain correlation exists between the narcotic effect of barbiturates and their ability to depress the respiration in an isolated liver mitochondrial system. This prompted me to see if ββ-methylethyl glutarimide exerted an antagonistic effect on barbiturates in this system.

Mitochondria were prepared from rat-liver homogenates made in 0·25 *M* sucrose[3] containing 0·01 *M* ethylenediaminetetraacetic acid (versene)[4], and incubated in the presence of glutamate, orthophosphate, adenylic acid, glucose and yeast hexokinase. The amytal (5-ethyl-5-*iso*amylbarbituric acid) used was an ordinary commercial product. The ββ-methylethyl glutarimide was a sterile solution containing 50 mgm. in 10 ml. of normal saline ('Migimide' from Nicholas Products Laboratories, Ltd., Slough).

It appears from Table 1 that the oxygen consumption of the mitochondria decreased with increasing amytal concentrations. Addition of ββ-methylethyl glutarimide, 0·8 and 1·6 μmoles/ml., had no effect on the oxygen consumption, whereas ββ-methylethyl glutarimide in concentrations of 3·2

Each Warburg vessel contained: mitochondria, 1/12-rat liver; glycylglycine, 200 μM; potassium chloride, 150 μM; glucose, 200 μM; *dl*-glutamate, 60 μM; orthophosphate, 100 μM; adenylic acid, 6 μM; magnesium ions, 6 μM; yeast hexokinase ('step-5' purity according to Berger *et al.* (ref. 5), preparation from 11 kgm. yeast dissolved in 30 ml. of 1 per cent glucose), 0 1 ml. Final volume 2·2 ml., *p*H 7·6. Temperature 30° C.: gas phase, air. Time of incubation, 30 min.

µmoles/ml. or more depressed the oxygen consumption. If ββ-methylethyl glutarimide was added to mitochondria, the oxygen consumption of which had beforehand been inhibited by amytal, low concentrations did not exert any effect, whereas higher concentrations which *per se* inhibit the oxygen consumption of the mitochondria intensified the depressing action of amytal.

Thus, the investigation did not disclose any antagonistic effect of ββ-methylethyl glutarimide on amytal in this system. On the contrary, in higher concentrations it intensified the depressing action of amytal on the mitochondrial respiration.

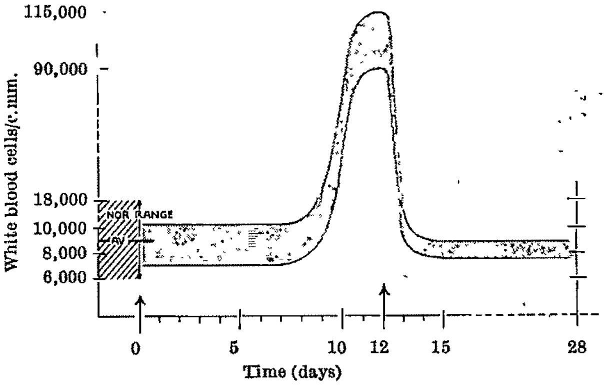
Remission of Rat Lymphocytic Leukæmia 8 following Intravenous Administration of 4-(*p*-Diethylaminostyryl)quinoline Dihydrochloride

Earlier studies[1] indicated that oral administration of certain styryl quinolines resulted in complete absorption of lymphoma 8 growing in inbred rats of the strain of its spontaneous origin. The neoplastic cells of this lymphoma appear in the bloodstream of the host animal as early as 18 hr. after subcutaneous implantation[2] and increase greatly, in some instances, to as many as 100,000 per c.mm. in the eighteen to twenty-one days before death of the rat. Intraperitoneal injection of 1 ml. of this lymphogenous blood into normal rats of the same strain produces a lymphocytic blood picture which bears a resemblance to certain types of clinical lymphocytic leukæmia. This lymphocytic leukæmia (rat lymphocytic leukæmia 8) is always fatal within twelve to twenty days. In view of their anti-lymphoma action, it seemed of interest to determine whether styryl quinolines, intravenously administered, would have any effect on this type of leukæmia in rats.

The two compounds, 4-(*p*-dimethylaminostyryl)-quinoline and 4-(*p*-diethylaminostyryl)quinoline, which possessed the greatest anti-lymphoma properties, are not soluble in water and only slightly soluble in propylene glycol. Among the compounds which we synthesized, two (the mono- and the di-hydrochloride of 4-(*p*-diethylaminostyryl)quinoline) were soluble in aqueous solution. The dihydrochloride, being the more soluble, was selected for this study.

The sixteen rats in our experimental series varied in weight from 150 to 200 gm. Each rat was injected intraperitoneally with 1 ml. of lymphogenous blood (from the heart) of a rat in which lymphoma 8 had been implanted subcutaneously fourteen to eighteen days previously. The number of white cells present in blood of normal rats is more variable than that of humans. Counts range from 6,000 to 18,000, with an average of 9,000 per c.mm.; the majority (60–70 per cent) of the white blood cells are lymphocytes rather than polymorphonuclear neutrophils. As shown in Fig. 1, the white cells in the blood increased slowly during the first five to seven days after transmission of the disease; the number then rose rapidly, reaching as high as 115,000 per c.mm. twelve days after the intraperitoneal injection. Stained preparations (Wright's stain) of the blood of untreated rats showed numerous large lymphoblast-like cells, some in mitotic division. On the twelfth day all the rats were extremely ill. On this day, twelve of the rats were each given a single intravenous injection of 4 mgm. of 4-(*p*-diethylaminostyryl)quinoline dihydrochloride dissolved in ¼ ml. of sterile distilled water. The remaining four rats were not treated. On the following day the four untreated and one treated rat were dead. On the second day after treatment, the surviving eleven rats had recovered their vigour, and the white blood cells had dropped to 8,500–10,000 per c.mm. (Fig. 1). On the third day after treatment, the white blood cells were 7,500–9,500 per c.mm. The rats gained weight and the white blood cells remained at this level during the following fourteen days (Fig. 1). In stained blood smears during this



Arrow at 0 days marks an intraperitoneal injection of 1 ml. of blood from rat lymphoma 8; arrow at 12 days marks an intravenous injection of 4 mgm. of 4-(*p*-dimethylaminostyryl)quinoline dihydrochloride

Fig. 1. Total white blood-cell counts in rat lymphocytic leukæmia 8 before and after intravenous administration of 4-(*p*-diethylaminostyryl)quinoline dihydrochloride. Normal range, hatched; average, stippled

period, only normal white cells could be found. The large lymphoblasts present in the blood before treatment seemed to have disappeared entirely.

These results seem to indicate that the intravenous administration of 4 mgm. of 4-(*p*-diethylaminostyryl)-quinoline dihydrochloride was followed by a remission of the leukæmic blood picture in rat lymphocytic leukæmia 8, but not by a depression of the total white count below the normal level in a fourteen-day observation period.

This investigation was supported in part by grants from the Pew Memorial Foundation and the Medical Research Foundation and in part by grant *C*-285(*C*7) from the National Cancer Institute, Department of Health, Education and Welfare.

Responses of Domestic Animals to Infections of *Trypanosoma vivax*, *T. congolense* and *T. brucei*

In an extensive investigation, involving more than a hundred domestic animals in the Gold Coast (goats, sheep and horses), on the hæmatological and biochemical changes produced by trypanosomiasis infections, forty animals have died with noteworthy findings.

The types of response could be arranged in four categories: acute, sub-acute, chronic and cryptic. In most cases, the animals developed a severe anæmia which in the acute response proved rapidly fatal (about six weeks). An attempt at recovery of erythrocyte values was made in the sub-acute response, followed by a fall which terminated in death in about three months from inoculation. Chronic responses showed an initial fall in red cells with subsequent recovery, often to normal levels, which was maintained over a long period. Of the animals which have died in the chronic response group, there was often a terminal fall in red-cell count. In the cryptic infections in which no trypanosomes were demonstrable in the peripheral blood, there were characteristic changes in the red-cell count which resulted in anæmia similar to that observed in the other categories. The erythrocyte sedimentation-rate in the goats remained normal (0–1 mm.) throughout the entire period, while in the sheep and horses it gradually increased. The leucocytes fluctuated in total count and the differential percentages varied, but they have not, as yet, been correlated with other recorded data.

An improved method of estimating the degree of trypanosome infection in the peripheral blood has been devised. Wide variation occurred from day to day in the number of trypanosomes in the *T. vivax* and *T. congolense* infections, with long periods when none could be found in the peripheral blood. In the case of *T. brucei*, trypanosomes were only seen on one or two occasions even though the infection extended over several months. This is of interest in view of the low incidence of *T. brucei* hitherto recorded in game and domestic animals of the Gold Coast. No trypanosomes occurred in the peripheral blood in cryptic infections.

Blood sugar, bilirubin and specific gravity remained unchanged in most of the animals. In the final stages of the disease, the animals were often emaciated and showed a severe reduction in weight. Temperature readings revealed no significant variations.

Histopathological material was collected from all the dead animals, some of which showed interesting pathological changes in the lung tissue with extensive congestion of the alveoli.

A detailed account of this investigation will be published elsewhere, as well as a report of the histopathology.

5-Hydroxytryptamine in Serum

The pharmacologically active substance 5-hydroxytryptamine is known to be liberated from platelets during clotting. The amount estimated in serum has, however, been found to depend on the way the serum is prepared, and the purpose of this communication is to direct attention to this phenomenon, which may cause discrepancies between the results of different workers.

Human blood was withdrawn from an arm vein into a glass syringe which had been treated with a liquid silicone (D.C. 550). The first 2 ml. of blood was taken in a separate syringe and discarded to avoid contamination with tissue thromboplastin.

The blood was allowed to clot at 37° C. in the following ways: (1) The blood was placed in a glass test-tube and allowed to stand without agitation for 30 min.; (2) the blood was placed in a glass test-tube containing a glass marble; the tube was stoppered and placed in a machine which tipped the tube through ± 20° from horizontal at a rate of 15 cycles per min., for 30 min.

In each case the clotted blood was centrifuged at 3,000 rev./min. for 30 min., by which time the serum was free of platelets. The serum was transferred to a small glass bottle and stored at − 17° C. until extracted.

Acetone extracts of the serum were assayed on the rat uterus, as recommended by Amin, Crawford and Gaddum[1]. An attempt to simplify this procedure by testing the serum directly on the uterus was unsuccessful owing to the presence in the serum of a substance causing a slow contraction of the uterus and not antagonized by lysergic acid diethylamide. The effects of the acetone extracts were invariably abolished by this drug, as were those of 5-hydroxytryptamine itself. Zucker and Borrelli[2] tested serum directly on the rat colon and do not seem to have met complications.

Table 1. 5-HYDROXYTRYPTAMINE EQUIVALENT OF SERUM (μGM./L.)

Stationary	160	154
Tipped	116	75

The results in Table 1 indicate that agitation during clotting results in a decreased amount of 5-hydroxytryptamine in the serum.

In another experiment a large amount of serum was prepared without agitation. Part of this serum was then tipped, part was allowed to stand, and part was tipped with added clot, all at 37° C. for 30 min. There was no significant difference between the 5-hydroxytryptamine equivalents of these three fractions, and none could be extracted from the clot. This result suggests that the clot does not adsorb 5-hydroxytryptamine and that mechanical disturbance after clotting even in the presence of the clot does not destroy it.

If serum is tipped during clotting, as recommended by Biggs and Douglas[3] for thromboplastin generation tests, its 5-hydroxytryptamine equivalent is likely to be lower than that of serum prepared without tipping.

Thanks are due to Dr. G. D. Forwell for assistance in preparation of serum samples.

Phosphorylation as a Possible Factor in the Pasteur Effect in Plants

AFTER the discovery of the participation of phosphate in glycolysis, suggestions that the Pasteur effect might be explicable in terms of the different rates of aerobic and anaerobic phosphorylation were made by Lennerstrand[1], Turner[2] and especially by Johnson[3]. In modern terms, the conservation of carbon by oxygen, which has been defined as the Pasteur effect, could be due to oxidative phosphorylation lowering the concentration of inorganic phosphate, or the ratio of adenosine di- to adenosine tri-phosphate, to levels which would limit the rate of glycolysis. The development of methods for measuring the concentration of these substances enables investigation of this hypothesis. The work to date has been restricted to measurements in the developing pea seed, in which the concentration of the phosphate esters is relatively high, and for which satisfactory analytical methods have been developed.

A typical experiment utilized six comparable samples of pea seeds taken from two pods past commercial maturity, each sample comprising two seeds, one from each pod. The testas were removed from all seeds (because they were shown to restrict gaseous diffusion), and the peas were placed overnight in water-saturated air. The experimental procedure is outlined, together with a typical respiration-rate curve, in Fig. 1. For each analysis the vessel was removed from the manometer, quickly stoppered, taken to a cold room and the seeds extracted by grinding with a small glass pestle and mortar with 3 ml. 5 per cent perchloric acid. The extract was centrifuged, the supernatant solution neutralized with potassium hydroxide and held overnight at – 15° C. Next day the material was thawed and the precipitate (potassium perchlorate) removed by centrifugation. The concentrations of adenosine tri- and di-phosphate, hexose monophosphate (the sum of glucose 1-phosphate, glucose 6-phosphate and fructose 6-phosphate) and hexose diphosphate (fructose 1 : 6-diphosphate) in each extract were measured by the method of Slater[4], the concentration of inorganic phosphate by the method of Allen[5] or of Weil-Malherbe and Green[6]. The respiration of each sample of two peas was measured in oxygen at 25° by the manometric method of Dickens and Simer[7]. After the tipping of the acid and the measurement of the carbon dioxide output, the vessel was flushed with pure nitrogen gas, and the succeeding pressure differences recorded gave a measure of the rate of fermentation, as shown in Fig. 1. The mean R.Q. of the seed without testa was 0·87 ± 0·01 (13 observations); that of the seed with testa in oxygen, or without testa in air, was about 1·1, which suggests that some fermentation occurs under these conditions due to the high diffusion resistance of the seed coat and cotyledon. In Fig. 1 the respiration-rates are plotted as production of carbon dioxide.

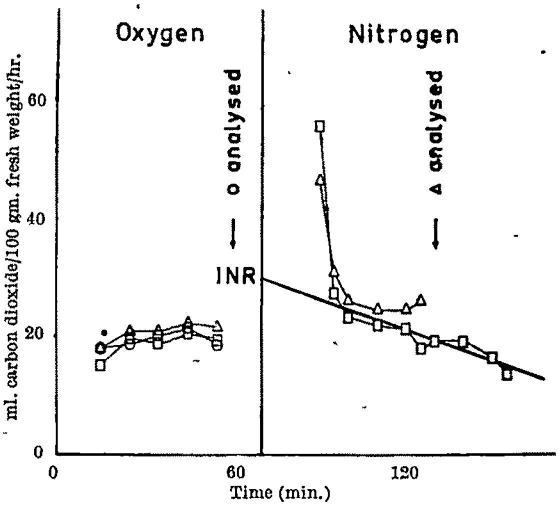

Fig. 1. Rate curves of respiration and fermentation of mature peas, showing the sampling periods for estimate of phosphate fractions. Dickens–Simer apparatus; 25° C. Each experiment utilized twelve seeds, each sample of two seeds. At the arrows, sample(s) were removed for the determination of phosphate fractions

It is difficult to know how to estimate the initial rate of fermentation. The very high initial values for production of carbon dioxide in nitrogen have been shown to be correlated with the initial low carbon dioxide partial pressure in the vessel, and may be due to rapid decarboxylation under these conditions. As the respiration measurements are made in the presence of baryta, it may be better to use these high figures. For the time being, however, we have extrapolated the rates measured in nitrogen to zero time in nitrogen, neglecting the initial high figures obtained within 30 min. after transfer to nitrogen (Fig. 1). These extrapolations will give minimum figures for initial rate of fermentation and, therefore, for the Pasteur effect. The value of the ratio of initial rate of fermentation to carbon dioxide production varied

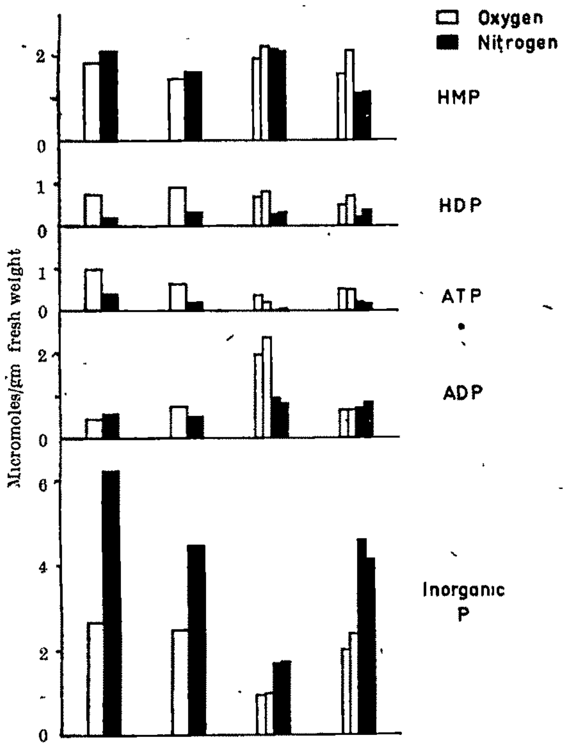

Fig. 2. Results of experiments of the type illustrated in Fig. 1, showing the change in phosphate fractions on transference from oxygen to nitrogen

when so measured from 1 to 1·6. H. G. Wager (private communication) has found that in the first three hours after transfer of pea seed to nitrogen, ethanol, equivalent to about 40 per cent of the carbon dioxide, was produced and, in addition, some acetaldehyde and lactic acid were formed in mature peas. It seems reasonable, therefore, to assume that the high values for this ratio indicate the existence of a Pasteur effect; its extent in these preliminary experiments cannot be measured.

Table 1

Experiment	Adenosine diphosphate / Adenosine triphosphate Oxygen	Nitrogen
1	0 4	1·4
2	1 2	2 3
3	7·6*	18·2*
4	1·3*	4·0*

* Mean of two extractions.

Fig. 2 and Table 1 show the analytical results of all experiments in which tissue was transferred from aerobic to anaerobic conditions. The concentrations of adenosine triphosphate and hexose diphosphate fell consistently in all experiments; inorganic phosphate and the ratio of adenosine di- to tri-phosphate increased. These changes occurred within 1 hr. (in one experiment within 30 min.) of the transfer to nitrogen gas, and their rapidity is of interest when it is remembered that the hypothesis of oxidative anabolism (resynthesis of glycolytic product[8]) is only valid if the transfer to anaerobiosis involves no rapid change in the rate of glycolysis.

These changes of concentration might stimulate the following reactions in glycolysis and starch breakdown:

$$\text{Starch} + P_i \rightleftharpoons \text{glucose 1-phosphate}$$
$$\text{Glyceraldehyde 3-phosphate} + \text{DPN}_{\text{ox.}} + P_i + \text{ADP} \rightleftharpoons \text{glycerate 3-phosphate} + \text{ATP} + \text{DPN}_{\text{red.}}$$
$$\textit{Enol}\text{pyruvate 2-phosphate} + \text{ADP} \rightleftharpoons \text{ATP} + \text{pyruvate}$$

The results reported are consistent with the hypothesis that on transfer from oxygen to nitrogen there is a rapid increase in concentration of inorganic phosphate and of the ratio of adenosine di- to tri-phosphate. This could give rise to an increased glycolysis, and so explain the Pasteur effect. Further work is envisaged on plants in which this effect is lacking.

Tripping, Crossing and Selfing in Lucerne Strains

There is some controversy on the proportion of lucerne flowers which set seed without tripping; but all investigators have agreed that tripping is essential for high yield of seed. Insect-tripped florets bring about cross-pollination and normally cross-fertilization, while seed setting without tripping or due to automatic tripping results usually in self-pollination and self-fertilization. The population of wild bees, although playing a most effective part in tripping and crossing, is inadequate. The importance of honey bees in tripping has been one of the most controversial subjects; but a number of investigators[1-3] showed that pollen-gathering bees caused a high percentage of tripping and nectar-gathering bees caused only accidental tripping.

There is no evidence as to whether the different strains vary in the amount of florets tripped, either self- or cross-fertilized, or in the number of pods and seeds set under comparable conditions. These aspects and the influence of weather and insects on them have been studied at the National Institute of Agricultural Botany (1953–55) in a number of strains planted as single-spaced plants in the field. Pilot investigations in 1953 showed that early strains (Eynsford, Du Puits, Chartrainvilliers and *W*.268) had a higher number of florets per raceme and, under natural conditions, a higher percentage of florets tripped and pods formed than in mid-season strains (Provence and New Zealand Strain *B*) and in late strains (Grimm and Rhizoma). The early strains also had a higher percentage of self-fertilized florets than mid-season or late strains under cover (my classification[4]). As the number of tripped florets was recorded and calyces marked each day, it was possible to correlate the

results with daily weather records. Correlations derived from the means for each strain for ten to fourteen days were highly significant.

More detailed investigations were carried out during 1954–55 with Eynsford, Du Puits, Provence and Grimm strains. Some results for 1955 showing the main differences between strains are given in Table 1.

The number of florets tripped and pods and seeds set under natural conditions in (*A*) treatment was similar for Eynsford and Du Puits. Also, the difference between Provence and Grimm was small; but the difference between them and the early strains was highly significant. Eynsford and Du Puits had the highest number of florets per raceme, percentage of tripped florets and number of pods formed. They also had a higher percentage of self-fertilized florets under cover (*D*) than Provence or Grimm, but this difference was small in treatment *B*. The difference in percentage of pods and seed per pod set under artificial tripping and crossing (*C*) between strains is negligible, but it is considerable between early strains and Provence or Grimm in the actual number of pods and consequently total number of seeds set. In Provence and Grimm the percentage of tripped florets under natural conditions (*A*), artificially selfed florets and pods formed in (*B*) and artificially crossed florets and pods set in (*C*) are in agreement with the figures obtained by Pharis and Urau[4] for similar treatments on an unspecified strain. When the number of seeds set per pod in treatment (*A*) is compared with that obtained in either treatment (*B*) or (*D*), a 2 to 1 ratio is obtained. This is similar to the ratio stated by other investigators[5,6] under similar conditions. However, none of these investigators used early strains or indeed specified the strains used in their experiments; whereas the present investigation shows that the greatest difference is between early strains and mid-season or late strains. I observed when doing artificial tripping and crossing that the early strains tripped more easily than mid-season or late strains. The ease with which they tripped is possibly the most important factor governing the greater number of pods set, as the other pollinating agencies, for example, honey bees, sun and wind, could trip a higher proportion of florets.

My own observation on honey bees was that they work in great numbers on lucerne, taking nectar from the side of the flower, as Reinhardt[2] showed, but causing accidental tripping on other florets on which they landed. They might also cause the cross-pollination of some automatically tripped or wind-tripped florets. The part played by other small insects mentioned by some investigators[3,6,7] should not be under-estimated. They are probably responsible for the fact that I and also others[3,7] found a much higher number of pods formed on selfing in the open than under continuously covered conditions. In the present investigation the range of the number of seeds per pod set under cover (*D*) was only 1–3 and none of the pods produced a full spiral, whereas in the open (treatment *B*), it was 1–5 and a few pods had 2–3 spirals formed. This would support the hypothesis of small insects helping in cross-pollination.

The report on this investigation will be published in full elsewhere.

Fixity in Chromosome Number of Plants

Studies on the chromosome behaviour of a large number of vegetatively propagating plants have revealed certain interesting facts. The investigations have mainly centred around members of the Aroideae, Liliaceae, Amaryllidaceae and Dioscoreaceae, including the ornamental ones, especially those with obligate vegetative multiplication[1].

In more than a hundred species of plants so far investigated, no constancy in the chromosome numbers of the somatic cells, even of the same root-tip, was found, and similar results are being accumulated from different groups of plants under investigation. In addition to the normal somatic chromosome number, which occurs with high frequency in the nuclei, irregular numbers of chromosomes are present in numerous cells. No regularity in the sequence of their occurrence was noted and the numbers so far recorded suggest random behaviour. This interesting phenomenon was first noticed in *Caladium bicolor*[1], and on careful scrutiny, the presence of irregular chromosome numbers is gradually being revealed in other species, of which species of *Hemerocallis*, *Haemanthus* and *Crinum* may be cited. In *Hemerocallis citrina* the normal somatic number is 22, whereas complements with 11, 18 and 20 chromosomes also occur frequently in the cells of the same root-tip. Similarly, in *Haemanthus kalbreyeri*, with $2n = 18$ chromosomes, and *Crinum kunthianum*, with $2n = 22$ chromosomes, abnormal numbers, such as 15, $16+f$, 17, $17+f$, $18+2f$, 20, $20+f$, 21 and 10, 12, 13, 14, 15, 17, 18, 20, 23, 24, 25 chromosomes respectively, have been recorded in different cells. The irregularities in these plants not only involve a numerical change but structural alterations are also recorded in cells otherwise showing a normal number of chromosomes. In species of *Hemerocallis*, etc., different individuals of the same species differ in the karyotypes of the normal cells, even if these do not differ in chromosome number. In these groups of plants, where sexual reproduction is ineffective, such variations may lead to speciation through their presence on the growing tips of daughter offshoots[2]. Experimental attempts to secure direct evidence of their role in speciation are yielding promising results.

This peculiarity in chromosome behaviour strongly emphasizes the necessity of an extremely cautious approach when investigating the number and behaviour of chromosomes in plants multiplying by vegetative means. The discrepancies often noted in the reports of chromosome numbers of the same species by different authors are significant in this connexion. It is apparent that the idea of the constancy of the chromosome number in cells is not strictly applicable to all plants.

Some Problems associated with determining Iron in Plants

It is well known that the total iron content of leaves determined by chemical methods seldom reflects the true iron status of plants. In instances of lime-induced chlorosis in fruit trees[1] or metal-induced iron-deficiency in crop plants[2], the iron content of chlorotic leaves is often reported to be similar or even higher than that of green leaves.

Various workers have shown that the iron determined by leaf analysis is considerably less after washing the leaves either in water containing a detergent or in dilute hydrochloric acid[3]. This difference has been assumed to result from the removal of iron contamination on leaf surfaces, although it has not hitherto been determined whether or not iron is leached from the tissues during leaf washing.

We have found that iron is a serious contaminant on the leaves of tomato grown in a glasshouse, and that it may be removed readily by washing the plant in water containing 0·3 per cent detergent.

The effect of duration of leaf washing on the iron content of tomato 'tops' was investigated as follows: The tomato plants, nine weeks from seed, were cut at approximately 6 in. above soil-level and immersed and well agitated in 0·3 per cent 'Teepol' in distilled water, drained for 5 sec. and then rinsed in distilled water. The results are shown in Fig. 1; half of each time interval was used for the detergent wash and the remainder for water rinsing. Significant amounts of iron were removed during the first 20-sec. washing period, but additional treatment did not further reduce iron. The manganese content of the plants, which is similar to their iron status, was unchanged by the washing treatment. Potassium, which is more readily leached than other nutrients, was also unaffected by this treatment. That the iron is remove from the external surfaces only is shown by the fac that the iron content of leaves of tomato plant grown in a dust-proof chamber remained unchange after washing, and their iron content was comparabl with that of washed leaves of plants grown in th open glasshouse.

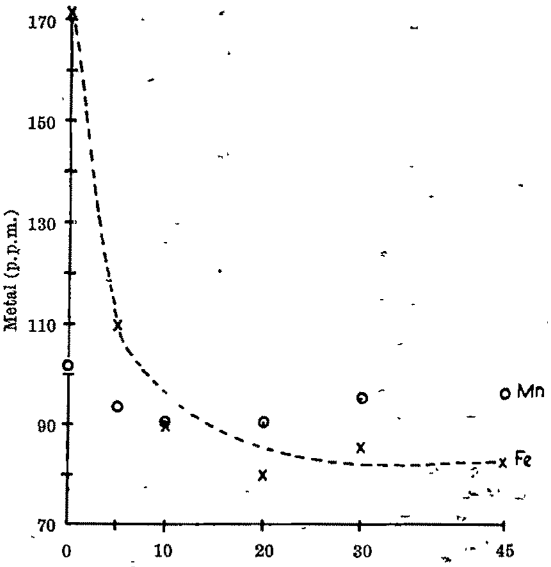

Fig. 1. Iron and manganese contents of tomato leaves after washing them for various periods in 0·3 per cent detergent and distilled water

The following experiment was carried out wit radioactive iron to determine whether iron was los from the plant tissues during washing: Tomat plants, var. Market King, were grown from seed i a complete culture solution containing 1 mgm. c iron labelled with 4 μc. of iron-59 per litre. Si nine and twelve weeks after seed germination th tops were washed, dried and the iron content of th wash solutions and the plants determined by chemica and tracer methods. The results are given in Table I

Washing the plant 'tops' for between 30- an 90-sec. periods in detergent and water resulte in a large loss of iron from the external surfaces but there was no appreciable loss of iron from th plant tissues, as is clearly shown by the low radioactive assay values for iron-59 in the wash solution The greater amount of tracer iron in each initia wash may have been caused by abrasion of glandula hairs.

In other experiments the iron content of dried an ground sub-samples of washed leaves were found t be less variable than those of unwashed specimens suggesting that the unequal distribution of iron contamination on leaf surfaces was the main cause o the variation noted.

It has been suggested that the adsorption of iro on silica and the formation of soluble iron complexe during acid digestion interferes seriously with iro analysis of plants[4]. In our experiments, however tracer and non-radioactive iron were recovered full when added at various stages during nitric an perchloric acid digestion of different dried plan materials, which are specially chosen to represent a range of silica contents[5]. Further, in tomato plant containing radioactive iron there was no indicatio

Table 1. Effect of Washing with Detergent and Water on the Removal of Iron from Tomato Plants

Leaf washing procedure: sequence and duration	(1) μgm. iron leached from plant 'tops', determined by the tracer method	(2) (1) as percentage of total iron in plant 'tops'	(3) μgm. iron in the wash solutions, determined by chemical methods (surface iron)	(4) (3) as percentage of total iron in plant 'tops'
Experiment 1 (6 weeks after germination) 0·3 per cent Detergent in distilled water (10 sec.)	0·24 ± 0·05	0·2	87	51
Distilled water (10 sec.)	0·10 ± 0·08			
Distilled water (10 sec.)	< 0·01			
Experiment 2 (9 weeks after germination) 0·3 per cent Detergent in distilled water (20 sec.)	0·37 ± 0·06	0·3	86	33
0·15 per cent Detergent in distilled water (20 sec.)	0·27 ± 0·05			
Distilled water (20 sec.)	0·09 ± 0·06			
Experiment 3 (12 weeks after germination) 0·3 per cent Detergent in distilled water (30 sec.)	0·68 ± 0·08	0·6	74	31
Distilled water (30 sec.)	0·25 ± 0·07			
Distilled water (30 sec.)	0·17 ± 0·06			

that the iron content of acid digests of plant 'tops' determined chemically by α-α-dipyridyl was less than that determined by the tracer method, thus demonstrating that soluble iron complexes, even should they be formed during acid digestion, did not interfere with the determination of iron in tomato.

A full account of this and related work will appear elsewhere.

A New Type of Male Fructification referable to *Glossopteris*

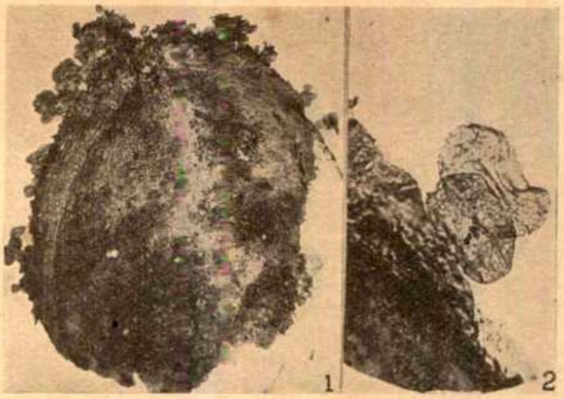

Fig. 1. Photomicrograph showing a dehisced pollen sac liberating numerous Lower Gondwana *Pityosporites* type of pollen grains. × 30

Fig. 2. Photomicrograph showing a pair of characteristic Lower Gondwana *Pityosporites* type of pollen grains on the dehisced wall of the pollen sac shown in Fig. 1. × 260

In a recent communication[1], I described several types of pollen sac containing typical *Pityosporites* type of pollen from some Raniganj (Upper Permian) coal, Lower Gondwana, India. For some years now, the members of the Lower Gondwana *Pityosporites* have been assumed to be the pollen of *Glossopteris*, because both the genera occur profusely and in close association throughout the system[2]. If such a relationship between *Pityosporites* and *Glossopteris* is acceptable, naturally, therefore, the sacs containing the *Pityosporites* should be regarded as the male fructifications of the *Glossopteris*. If this proposed relationship is established, the morphological value of the male fructifications described here, and in a previous communication[1], may have some bearing in determining the systematic position of *Glossopteris*, since considerable doubt now exists as to the structure of the male fructifications of the genus.

A new type of sac containing *Pityosporites* type of pollen (Figs. 1–2) from coal of Karharbari stage (Lower Permian) of the Lower Gondwana, India, has now been found. This differs from those previously described[1] in (1) the manner of dehiscence, and (2) its general shape and structure. It is thus a new member of the previously reported group of male fructifications referable to *Glossopteris*.

The new type of pollen sac is free and occurs singly in maceration residues, exannutate, apparently sessile, more or less oval with the base broader than the apical region (which is a very short and slightly raised cylindrical structure), unilocular, dehiscing regularly along a median line of dehiscence from the apex in a longitudinal direction; as a result the sac splits into two equal halves which are attached towards the base and thus liberates typical pollen of *Pityosporites* type (Figs. 1–2). The cell structures of the sac are mostly destroyed; in some places, however, they are faintly visible (but not reproducible photographically). The cells along the line of dehiscence are linear, with mostly irregularly and laterally thickened walls (Fig. 3) where the sac bursts, and the cells become progressively shorter and broader away from the region of dehiscence and thus usually appear as rectangular structures (Fig. 4). The whole pollen sac measures 1,440μ × 1,100μ. A structure of this size can easily be accommodated in the sorus-like body borne by a *Glossopteris*[4].

The pollen grains are typically Lower Gondwana type of *Pityosporites* previously described by many authors. Each grain is provided with two lateral reticulately marked bladders placed on opposite sides of the thickly rimmed more or less elliptical body, which consists of a number of horizontal stripes

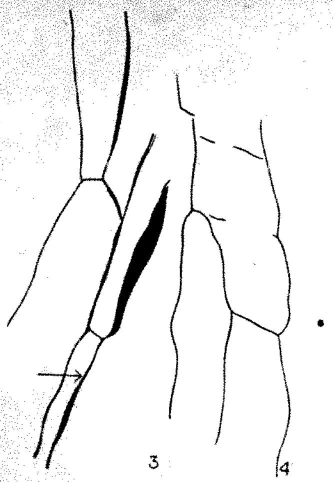

Fig. 3. Camera lucida sketch of some characteristic cells of the line of dehiscence (shown by an arrow head) of the pollen sac with irregular thickening in the walls, mostly restricted towards the actual line of dehiscence. × 425

Fig. 4. Camera lucida sketch of some characteristic cells of the pollen sac wall away from the line of dehiscence. × 425

(Fig. 2). The size varies from 58μ to 80μ (from bladder tip to bladder tip).

Such different types of fructifications—as described here with longitudinal dehiscence, and others previously described[1] with primarily transverse mechanism of dehiscence—do not usually occur in the same genus. However, the tendency towards longitudinal dehiscence as a secondary adaptation for pollen dispersal after the first clear transverse dehiscence is quite clear in some of the pollen sacs described previously[1]. These may be regarded as intermediate forms. It is now time to question whether *Glossopteris*, possibly bearing pollen sacs of characteristically different nature as discussed here and previously[1,4], is a well-knit genus. The ovulate fructifications are also not of the same type[5].

Effects of Cyanide on the Roots of *Vicia faba*

Mottram[1] claimed that cyanide ions had a considerable effect on the radiosensitivity of *Vicia faba* as measured by growth-rate reactions. Read[2] was unable to confirm this, and Thoday found (unpublished results) no effect upon chromosome breakage (which is often correlated with growth reactions[3]).

During the course of experimental work designed to investigate this apparent discrepancy, significant effects of cyanide independent of radiation have been discovered. The experiments involved four conditions. Roots were immersed in water or in $5 \times 10^{-4} M$ potassium cyanide at *p*H 7 for 30 min., and at the same time nitrogen or oxygen was bubbled through the vessel. At various intervals after such treatments, the lengths of the roots were measured and tips were fixed for cytological examination.

The measurements of length revealed significant effects of cyanide, primarily in the presence of oxygen. There is a similar effect on the progress of mitosis. Mitotic index (proportion of cells in metaphase, anaphase or telophase) is temporarily reduced after the period in nitrogen, and the reduction may be increased very slightly by cyanide. Oxygen alone produces little effect. Cyanide and oxygen together, however, produce a greater and more prolonged inhibition of mitosis.

Examination of anaphases revealed that the roots treated with cyanide in the presence of oxygen contained a much higher frequency of chromosome aberrations than those that received the other treatments (Table 1). There is no evidence of any effect of oxygen in the absence of cyanide or of cyanide in the absence of oxygen.

Table 1

Treatment		Time elapsing between treatment and fixation (hr.)										
		1½	3	6	9	10½	12	14	16	24	36	48
Nitrogen + water	Anaphases		100	100	100	100	100	100	100	100		
	% Abnormal		5	1	2	0	1	1	2	0		
Nitrogen + pot. cyanide	Anaphases		100	100	100	100	100	100	100	100		
	% Abnormal		0	4	1	2	0	0	0	0		
Oxygen + water	Anaphases	200	200	200	200		200		200	200	200	200
	% Abnormal	1	0	1	1		1		2	0	1	1
Oxygen + pot. cyanide	Anaphases	200	200	148*	46*		81*		96*	59†	200	200
	% Abnormal	15	23	10	39		26		21	29	14	2

* The low mitotic index at these times reduced the anaphases available below the 100 per root aimed at.
† Only one root examined as in the nitrogen experiments.

Other effects of cyanide have been reported, which may be of interest in considering the present experiments. Cyanide and azide are known to cause mutations[4,5]. It has been suggested that these substances cause the accumulation of peroxides by the inhibition of catalase[5] and that these peroxides may be involved in chromosomal disturbances[6]. It is known that cyanide and azide both inhibit the cytochrome system, and this inhibition may channel more of the aerobic respiration through the cyanide (azide)-insensitive flavoprotein system which can produce hydrogen peroxide[5,7]. Further, King *et al.* suggested that in high oxygen tension the flavoprotein systems have greater activity and more hydrogen peroxide may be formed.

It is possible, therefore, that the chromosome aberrations reported above are caused by peroxide, the formation of which may be partially influenced by oxygen tension.

The relation of cyanide to breakage is, however, complex, for when X-rays are used in conjunction with the other treatments, the effect of cyanide with oxygen disappears. Instead, there is an effect with cyanide in the absence of oxygen. These irradiation results will be the subject of a later report.

This investigation was carried out in Sheffield and was aided by a grant from the Department of Scientific and Industrial Research to one of us (L. J. L.), then in the University of Sheffield Department of Botany.

Living and Fossil Pollen from Macquarie Island

THE use of palynology to investigate the ancient floras of antarctic and subantarctic regions and to aid in explaining the present distribution of the living florula has been largely ignored. Auer[1] made use of pollen analysis to describe the fluctuations of forest and steppe vegetation in Tierra del Fuego in postglacial time. Cookson[2] described the pollen occurring in the tertiary lignites of the Kerguelen Archipelago. So far as I am aware, no workers have undertaken similar studies in any other part of this zone.

Macquarie Island (lat. 54° 30′ S., long. 158° 57′ E.), volcanic in origin, dates back to Early Tertiary or Middle Mesozoic time. It has been much reduced in size by block faulting and has undergone extreme glaciation during the last Ice Age. Fluvio-glacial deposits, considered by Mawson[3] to be postglacial in age, are fairly common and include well-developed bands of lignite.

While a member of the 1951 Australian National Antarctic Research Expedition based on Macquarie Island, I was able to obtain a series of lignite samples for examination. By extraction of pollen by the acetolysis method of Erdtman[4] and by comparison of the types discovered with those of the existing vascular flora (some thirty-eight species of grasses and small herbs), it has been possible to show an apparently complete disaffinity between the past and present vascular floras of the island. This finding strongly suggests that the lignites represent the remnants of a preglacial flora. Altogether seventeen main fossil pollen types were found, and it is of interest that these did not include *Nothofagus* or Gymnosperm-type pollens.

During the Ice Age, when the area of land in the vicinity of Macquarie Island was much greater than it is to-day, it is probable that, notwithstanding the severity of the glaciation, parts of the land mass were capable of supporting plant life. Such conditions exist at present in several parts of the subantarctic zone. With the recession of the ice sheet, it is reasonable to assume that the limited plant life began to colonize the freshly exposed land-surface. At the time when faulting and subsidence were practically complete, it is probable that small plant communities were able to survive in more favourable sites on the now much smaller land mass. Those communities may have formed the bands of lignite still preserved at Macquarie Island.

With the land mass greatly reduced in size, a reversal of conditions might readily result in complete extinction of the remnant flora. That such a reversal may have taken place is indicated by the fact that the lignites were found to be covered with considerable layers of fluvio-glacial rubble. Should this explanation be correct, then the fossil pollens may be closely related to the Tertiary floras of the Antarctic.

It is of interest that no definite affinities could be found between the fossil pollens of Macquarie Island and those described by Couper[5] from New Zealand. Although he has recorded compositous grains in deposits ranging from Miocene to Recent in age, without detailed descriptions it is not possible to decide whether any of these are identical with those occurring in the lignites of Macquarie Island.

A search of the available literature[4,6] has shown that the pollen of many species of the antarctic vascular flora has not been described. Until such descriptions become available, the identification of recent fossil pollen from this zone must remain uncertain.

A Direct Method for the Measurement of Cerebral Blood-flow

THE blood-flow through the rostral and parietal parts of the heparinized cat's brain has been measured by cannulating the sagittal sinus. This flow has been correlated with the systemic blood pressure and the electroencephalogram.

After longitudinal craniotomy in the midline, the sinus was ligated at its caudal end. On the rostral side of the ligature a thin polyethylene catheter was introduced into the sinus. The blood was directed to an electric drop recorder, connected with an 'ordinate recorder' which operated a galvanometer. The blood was then returned to the animal by intravenous drop infusion. The craniotomy interrupted the most

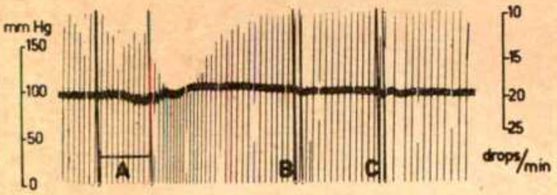

Fig. 1. Cat, 4·5 kgm. 'Nembutal' (40 mgm./kgm.). Vagus, cervical sympathetic trunk and the sinus nerve divided bilaterally. Blood pressure (thick line) from the femoral artery. Blood-flow from sinus sagittalis superior (vertical lines). Each drop of blood from the sinus rapidly carries the spot of the mirror galvanometer to the base of the figure, from which it returns at slower speed so that a steeply rising line is recorded. The length of these lines is directly proportional to time-interval between drops. By joining the upper ends of these lines one obtains a curve inversely proportional to blood-flow (cf. calibration on the right). The record is interrupted every 30 sec. (*A*) 10 per cent carbon dioxide in the inspired air; (*B*) twisting the pinna; (*C*) pinching the paw of the right foreleg. Note, large transient increase of blood-flow in *B*, slower increase in *A*, transient decrease of flow in *C*

important anastomoses between the sagittal sinus and the diploic veins. Ringer solution was injected through the catheter into the sinus in order to show that no larger anastomoses still existed between the sinus and other veins. Intravenous injections of a solution of indian ink and gelatine showed that the drainage was restricted to the rostral and parietal parts of the brain and did not include extra-cerebral areas. Even the jugular bulbs are known to hold only 2·6 per cent extra-cerebral blood[1].

The systemic blood pressure was recorded in the femoral artery by a strain-gauge instrument. The electroencephalogram was led off bipolarly from the middle suprasylvian or the cruciate gyrus.

This method has made it possible to demonstrate that variations in the cortical blood-flow may occur even when the systemic blood pressure is constant. Smaller changes in the blood pressure may be completely without effect on cerebral blood-flow. A larger change in blood pressure, on the other hand, was usually followed by a passive increase in the cerebral blood-flow. The well-known vasodilating effect of an increased concentration of carbon dioxide could easily be demonstrated (Fig. 1,*A*). Cerebral vasomotor reactions, reported to appear during changes in the electrical activity of the cortex[2], were likewise revealed in a very direct fashion. Thus, for example, in the lightly anæsthetized preparation, nociceptive stimuli, twisting the pinna and electrical stimulation of the reticular activating system produced transient changes in the cortical blood-flow. There was a latent period of about 2–5 sec. and a duration which paralleled the concomitant change in the arousal reaction of the electroencephalogram (Fig. 1,*B* and *C*).

Doses of adrenaline and noradrenaline which gave identical rises in the systemic blood pressure were found to produce different effects upon the cerebral blood-flow, the effect of adrenaline being the larger. Ergotamine, in most cases, was found to elicit an increase in the cerebral blood-flow. This effect will be described in detail elsewhere.

Deep anæsthesia abolished all kinds of vasomotor reactions in the cortical vessels. The vascular resistance, which in such circumstances remains constant, makes the cerebral blood-flow a direct function of the systemic blood pressure. Ether paralyses the cerebral vessels in the dilated state, while under barbiturates they are paralysed in a state of constriction. To judge by the electroencephalogram, the resistance of the vessels to anæsthetics corresponds roughly to the level of activity of the cortical neurones.

Action Potentials from Internal Laryngeal Muscles during Phonation

ELECTROMYOGRAPHY of the internal laryngeal muscles has been applied in the diagnosis of laryngeal palsy by Weddell, Feinstein and Pattle[1]. In a study of phonation, Katsuki[2] recorded action potentials from the m.crico-thyreoideus externus in a case with partial resection of the larynx. In the present study, action potentials were recorded by means of concentric needle electrodes inserted in the m.thyreo-arytaenoideus internus (m.vocalis), crico-thyreoideus externus, inter-arytaenoideus transversus and crico-arytaenoideus posterior (m.posticus) of normal subjects and of patients with laryngeal paresis. In addition,

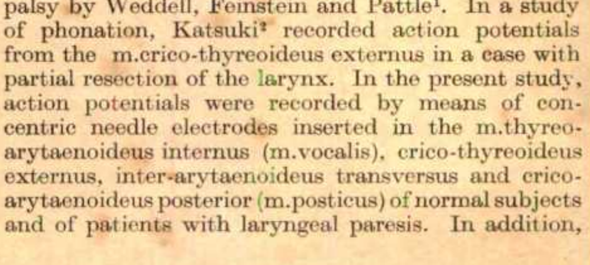

Fig. 1

(*A*) Subject A. H., 64 years; left m.thyreo-arytaenoideus internus, intonation of 'e', frequency 265 c./s. (*a*) Directly recorded action potentials; (*b*) mean action potential amplitude; (*c*) voice recorded on microphone

(*B*) Subject C. S., 55 years; right m.thyreo-arytaenoideus internus, intonation of 'e', frequency 285 c./s.; first with small, then with large intensity. (*a*) Directly recorded action potentials; (*b*) mean action potential amplitude; (*c*) voice recorded on microphone

(*C*) Subject A. J., 44 years; left side paresis of n.recurrens, intonation of 'e', frequency 263 c./s. (*a*) Directly recorded action potentials in left m.crico-thyreoideus externus; (*b*) directly recorded action potentials in left m.thyreo-arytaenoideus internus; (*c*) mean action potential amplitude in left m.thyreo-arytaenoideus internus; (*d*) voice recorded on microphone

(*D*) Subject F. B., 47 years; left crico-arytaenoideus posterior, intonation of 'a', frequency 200 c./s. (*a*) Directly recorded action potentials; (*b*) mean action potential amplitude; (*c*) voice recorded on microphone the action potential amplitude was averaged electrically and recorded as an expression of the degree of activity. The subject spoke into a condenser microphone, the output of which was amplified and recorded simultaneously with the action potentials.

An increase in activity occurred in the m.thyreo-arytaenoideus internus, crico-thyreoideus externus and inter-arytaenoideus transversus 0·3 sec. before any signal was observed on the microphone (Fig. 1,*A*, *B*,*C*). The degree of muscle activity increased greatly with increasing pitch as long as this obtained without change in register. Increase in tone volume had scarcely any effect on the degree of muscle activity (Fig. 1,*B*). As in other voluntary muscles, the increase in activity was due to an increase in the number of activated muscle fibres and in their frequency of discharge. In cases of laryngeal paresis it was possible to follow the increase in frequency for a single motor unit potential (from 10 to 50 per sec., Fig. 1,*C*). The activity was maximal before and in the very first period of intonation. Then it remained on a slightly lower level until intonation stopped. Activity was simultaneous in the m.thyreo-arytaenoideus internus, crico-thyreoideus externus and inter-arytaenoideus transversus.

The activity in the m.crico-arytaenoideus posterior was greatly inhibited during intonation (Fig. 1,*D*). The inhibition occurred 0·3 sec. before a signal appeared on the microphone.

If the subject was asked to prepare an intonation without voice production ('silent speech'), the initial burst of activity was still observed.

Role of the Terminal Pigment Spots of the Starfish, *Asterias forbesi*, in Light Orientation

IT is generally stated in standard reference and text-books of zoology that, in species where such bodies are present, the terminal pigment bodies (or 'eye spots') are necessary for light orientation. In two early studies, Romanes[1], in the "starfish", and Preyer[2], in *Asterina gibbosa* and *Asterias glacialis*, found that these spots were essential in the positive light responses of these starfish and that without these pigment bodies such responses were lacking. On the other hand, several contradictory reports have also appeared[3-5] which emphatically state that positively phototropic responses persist even after the excision of all the eye spots of each ray of *Echinaster crassispina*, *Pentaceros reticulatus* and *Asterias forbesi*. I therefore undertook to check the role of these pigment bodies in light orientation of the common starfish of the North Atlantic coast of North America south of Maine, *A. forbesi*, as well as to establish a possible chemical basis for light perception.

To this end two different sets of study were undertaken; observations were made of the ability of 'eyeless' and intact starfish to orient to light and concomitantly the absorption spectra were studied of extracts of pigments from these terminal bodies as well as from the dorsal skin of individuals of this species.

In the first case, the pigment body was removed from each of the rays of twenty starfish (about one and a half inches across, in size) by simple transverse cutting about one half-centimetre from the tip. These were then placed, together with an equal number of intact starfish of similar size, in a tank with running sea water, which was so illuminated by the light from a 100-watt Burton lamp (placed 18 in. from the end of the tank) that one side of the tank was illuminated by a narrow shaft of light parallel to the long axis of the tank. After all the starfish had been permitted to distribute themselves freely throughout the tank the number of normal and 'eyeless' animals to be found in the dark zone was counted. After each such observation all the starfish were replaced into the darkened (approximately $\frac{7}{8}$) portion of the tank and allowed to redistribute themselves for at least three (usually 10–12) hours before a subsequent tally was made. The following represents the results of such observations over a six-day period:

Trial No.	Intact starfish in dark zone	'Eyeless' starfish in dark zone
1	10	5
2	15	6
3	11	8
4	9	9
5	6	9
6	19	6
7	6	5

Although facilities for studies involving various portions of the visible light spectrum were not available, a second similar set of observations was made upon 26 eyeless and 26 normal starfish (1½–2 in. across) exposed to a similar narrow shaft of light from a Westinghouse 50-watt red safety lamp under otherwise identical conditions as above. In one case twelve normal and six eyeless, in a second observation five of each type of starfish were found in the dark part of the tank. Clearly, the eye spots are not essential for positively tropic responses by this species to light of this quality and intensity.

An obvious assumption from the above observations is that the skin of the species in question is sensitive to light. To establish a chemical basis for such sensitivity to light, extracts were prepared, directly as well as indirectly (through phosphate buffer followed by petroleum ether extractions), into a 2 per cent digitonin solution, from the eye spots and adjacent dorsal skin segments from animals of this species, previously dark-adapted in running sea water for at least sixteen hours. All preparations were made in the dark and comminution of tissues effected at 0–5° C. Spectral analyses of such extracts revealed an absorption spectrum with a sharp peak at close to 320 mμ and a secondary, broader and lower plateau at about 450–500 mμ, for each of the sets of extracts studied. Also, a minimum of thirty minutes exposure of each of these extracts to cooled, white light (from a 100-watt Mazda lamp), placed twelve inches from the cuvettes containing these extracts, resulted in a significant decline in the optical density thereof; this indicated the presence of a photosensitive pigment.

Obviously, therefore, both the skin and pigment bodies of this species possess a similar photosensitive chemical component which suggests that both have a common function in gross light perception, especially in the positively phototropic responsiveness of this animal. There remains, however, further clarification of the role of these pigment bodies in terms of possibly higher sensitivity than those of the dorsal skin to light of the same wave-lengths or in terms of possibly greater (if not specific) sensitivity to particular bands of the spectrum. What is contemplated is an additional behavioural study of the responsiveness of this species to various parts of the spectrum as well as concomitant spectral analyses of the extracted pigments before and after exposure to each of several bands of the light spectrum.

This work was carried out at the Woods Hole Marine Biological Laboratory Department of Physiology Laboratories; I am indebted to Dr. Daniel Mazia for making such facilities available for this study and to Dr. George Wald of Cornell University for his valuable suggestions concerning the chemical aspects of the work.

Failure of Enforced Hibernation to inhibit Breeding in the Frog (*Rana temporaria*)

IT is well known that the frog (*Rana temporaria*) is extremely tolerant of cold, and may continue to breed when ice covers or encrusts the sides of the ponds. Warmth, or a small transitory rise in temperature, however, may be necessary for breeding to be initiated.

Dr. M. Smith[1] suggests that the variability in time of spawning (apart from temperature) may be due to the phosphate content of the water and to the availability or otherwise of food for the tadpoles. The amount and the intensity of light are also thought to be important.

In view of these accepted facts, it seems worth while recording the following.

A group of male and female frogs, captured in East Anglia in late September 1954, were subjected to enforced hibernation in a domestic refrigerator early in October of the same year.

The thermostat in the refrigerator was set so that the temperature was maintained at 38° F. A maximum and minimum thermometer was put into the refrigerator and the temperature checked twice each day.

The animals were stored in a shallow enamel tray containing $1\frac{1}{2}$ in. of tap water and covered by a piece of hardboard drilled with several $\frac{1}{2}$-in. holes. The water in the tray was changed on alternate days. There was no pilot light in this particular refrigerator.

In mid-May 1955, $7\frac{1}{2}$ months after enforced hibernation had started, amplexus occurred in four pairs of animals and spawn was laid.

Spawn continued to be laid at intervals until early July. During this time, however, the animals were not always in amplexus. The spawn was removed from the refrigerator and put into shallow trays; some contained tap water and one contained rain water. The spawn in the rain water developed and the spawn in the tap water did not. By August 1955 the froglets from this spawn were approximately $1\frac{1}{2}$ cm. long and beginning to take adult frog laboratory food.

When the adult frogs spawned it is estimated that they had been exposed to light of average indoor intensity for half a minute on alternate days for $7\frac{1}{2}$ months, and warmth for the same period. They had, however, been exposed to cold tap water also on alternate days. Due to the large surface area, the water would probably only take 15–30 min. to attain the temperature of the refrigerator, that is, 38° F. It is probable that the phosphate content of the water varied little, and certainly there was no food available either for the adult frogs or for any potential tadpoles. It is noteworthy that not all the female animals spawned, and that the onset of breeding was substantially delayed in the others.

It is possible, and indeed probable, that there was a gradual build-up of the hormones necessary for breeding to occur; but it must be generally agreed that the external stimuli usually considered necessary for this to occur were minimal.

Status of *Protobatrachus massinoti*

THE history of the Amphibia Salientia can readily be traced back to the Jurassic when it appears that, skeletally at least, they were already typical, modern Anura. The pre-Jurassic history of frogs, however, was completely unknown until 1937 when Piveteau[1] described *Protobatrachus massinoti* from the lower Trias of Madagascar. To accommodate *Protobatrachus*, Piveteau defined a new order, the Proanura, differing from the Anura chiefly in possessing a tail but no urostyle and with the tibia and fibula, radius and ulna, unfused.

In excluding *Protobatrachus* from the Anura, Piveteau strongly emphasized that no analogy exists between the tail of modern frog tadpoles and the 'true' tail of *Protobatrachus* since, in the former, no vertebræ develop but only the notochord with its sheaths and enveloping skeletogenous layer. In a recent survey of anuran larvæ, however, I have examined tadpoles of the pelobatid *Megophrys major* and found that, from early larval stage, they possess about seventeen ossified caudal vertebræ—a condition that, so far as I am aware, has not hitherto been described for any other anuran larva. In the light of this discovery it seemed pertinent to re-examine Piveteau's statement and the status of *Protobatrachus*.

If *Protobatrachus* is regarded as an adult form two problems of functional morphology are posed. First, the animal possesses ilia, femora, tibiæ and fibulæ which, although relatively not as elongated as in the adults of modern frogs, are, nevertheless, clearly salientian adaptations and, consequently, a sacral articulation would be expected. But no sacrum appears to be present. Two vertebræ with backwardly directed ribs lie between the iliac arms, but they are quite free of the pelvic girdle; while, mesial to the heads of the ilia, where articulation normally occurs, the single vertebra present is unexpanded and unspecialized. How, then, can the salientian trends so clearly shown in the hind limbs and girdle, and which are so essentially concerned with transmission of thrust against the vertebral column, be correlated with the absence of a functional sacrum ? Secondly, as Piveteau appreciated, and as the nature of the caudal vertebræ suggests, the tail was much longer than the remains described by him. How can such an organ, so clearly incompatible with the salientian features listed above, be considered to have combined with them to form an efficient locomotory system ?

These morphological enigmata can logically be resolved by regarding *Protobatrachus* as a tadpole in the later stages of metamorphosis. The tail with its ossified vertebræ is now explicable as a larval, locomotory organ destined for resorption at metamorphosis as in the case of *Megophrys major*. This view can also account for the moderate lengths of the ilia and hind limb bones and for the absence of a sacrum, for these elements complete their development and are knit into a functional unit only towards the end of metamorphosis when, after the resorption of the tail, they form the locomotory organ of the adult. It may explain, too, the paucity of the anterior cranial elements for, at this stage, they would not be ossified to any degree.

A detailed account of the structure and development of the vertebral elements in *Megophrys major*, with a discussion on anuran phylogeny, will be published elsewhere.

Effect of Supplementary Choline and Methionine on the Response of Chickens to Folic Acid

The wide range of folic acid requirements of chickens reported by various authors[1] is partly explained by considerations of dietary and genetic factors known to affect requirements. Excess intake of choline[2] and glycine[3] has been shown to depress growth or produce anæmias which can be prevented by feeding supplementary folic acid. In experiments at this Station, the effect of choline on folic acid requirements has been confirmed, and supplementary methionine has been shown to have a similar effect.

Two experiments, observing the effect of supplements of 0·2 per cent *dl*-methionine and 0·066 per cent choline (providing an equivalent quantity of labile methyl groups as 0·2 per cent methionine) on the response to supplementary folic acid, have been completed using White Leghorn chickens up to six weeks old. The basal diet contained crushed wheat, meatmeal and whey powder. Dietary supplements and results are summarized in Table 1.

The response to methionine added as the sole supplement or together with folic acid in experiment 1, and in the presence of both choline and folic acid in experiment 2, shows that the diet was deficient in methionine and that the response was independent of the role of methionine as a methyl donor.

In experiment 1, the absence of response to folic acid alone, and the response following addition of folic acid to the diet supplemented with methionine, indicate that the chicken's requirements of folic acid were higher following methionine supplementation. In experiment 2, the growth depression following supplementation of the diet with choline and the effect of addition of folic acid in reversing this response suggest that the methionine – folic acid interaction observed in the first experiment was due to the labile methyl group in the molecule. These results indicate that folic acid is required for the catabolism of excess methyl groups as well as in transmethylation processes. As glycine also provides labile methyl groups[3], the effect of folic acid in reversing the toxicity of glycine further confirms this role of the vitamin.

Table 1. Effect of Methionine and Choline Supplements on the Growth Response of Chickens to a Folic Acid Supplement

		Supplements to basal diets		
Exp 1	Nil	4·4 p.p.m folic acid	0·2% *dl*-methionine	4·4 p.p.m. folic acid + 0·2% *dl*-methionine
Relative weights at 6 weeks (difference for significance $P <$ 0·05, 5 per cent)	100	98	112	120

		Supplements to basal diets		
Exp 2	Nil	0·066% choline	0·066% choline + 4·4 p.p.m folic acid	0·066% choline + 4·4 p.p.m folic acid + 0·2% methionine
Relative weights at 6 weeks (difference for significance $P <$ 0·05, 5 per cent)	100	83	101	106

Further details of these experiments will be published elsewhere.

Science Babel

While agreeing with the points made in the editorials of November 5 and 19, I may perhaps say that you reveal more than I think you were aware of when writing "a nation using . . . a minority language cannot escape bilingualism if it desires to attain high standards of culture and scholarship". If the sentence is understood as referring to the use of minor languages for publishing, it is indisputable ; but all too frequently it turns the other way—scholars within the major language groups neglecting the literature outside their own language. In fact, if we take into consideration languages read as well as written, no language group can to-day avoid even trilingualism if it wishes to attain the highest standards of culture and scholarship.

To illustrate this point I have made a small survey of world scientific literature within a comparatively narrow field, so that the authors have had the theoretical possibility of drawing from the same, rather well-circumscribed scientific heritage. Two botanical journals were used from each country or group of countries[1], one with a background of ecology, the other more general. The most recent issue(s) was (were) used, and at least ten papers were analysed. No issue was older than 1952.

The idea was that, whereas it is difficult to calculate how much scientific material is presented in different languages, it is comparatively easy, by studying the reference lists at the ends of the papers, to find out what is really utilized by fellow scientists.

Table 1

Country	No of papers	No. of titles in reference lists	Percentages								
			English	German	French	Russian	Scandinavian (coll.)	S European (coll.)	Latin	Dutch	Others
Britain	39	618	78	15	3	—	3	—	—	1	—
France	22	1,000	42	14	42	—	+	1	1	—	+
Germany	26	413	22	69	7	½	½	½	—	+	—
Scandinavia	25*	554	63	19	4	1	10	½	2½	—	—
Switzerland	30†	701	24	60	13	—	1	+	2	+	—
United States	38	679	84	11	4	—	+	+	—	+	?
U.S.S.R.	33	392	16	10	1	73	+	—	—	—	—

* 23 English, 1 German, 1 Swedish.
† 29 German, 1 French.

The results are given in Table 1. Its shortcomings are obvious, but the fact that the percentage figures from each pair of journals (from one country or area) were practically identical, may serve to give it more emphasis. The only exception was the Swiss pair, which showed considerable discrepancies.

That our Soviet colleagues know more about 'Western' literature than the reverse is nothing new; but it is deplorable. New to many others besides myself may be the high standard of polyglottism exhibited by the French literature. That the English and even more the American literature should emerge as the narrowest is scarcely unexpected, but it should be remembered that in this case the 'home' language is undoubtedly also the dominating one within the pool, which accounts for a double effect (one of the Swiss journals also had 80 per cent 'home' language).

The main lesson to be learnt from the table is what a waste it is to publish in anything but the three great languages (and even the inclusion of French among them may be questioned). There is to-day the possibility of publishing primary scientific material in a large number of different languages; but there is also the overwhelming possibility that anything published in a minor language will pass unrecognized and never enter the common pool of world scientific knowledge.

Because I have more than twenty years experience in publishing scientific material in two languages not my own, I think I may safely protest against the accusation that compulsion to write in a foreign language curtails the possibilities for intelligent communication. Admitting that there are exceptional brains, for which no rule can be laid down, I am convinced that a brain that has the capacity for scientific work has also the capacity to learn so much of at least one foreign language as to be able adequately to express scientific ideas in it.

It is a waste, and it is also inconsiderate, to publish primary scientific material in a minor language. Notwithstanding the fact that important works have been published in other languages, it is a fact that the great majority of those papers that are worth reading have been published in the three major languages—and in some branches of science also in Latin. Very few are born to more than one of these languages, the other ones have to be acquired: so far as reading goes, the difference between members of the great and small language groups is the difference between learning two or three foreign languages sufficiently well to use them. That is theory; I fear that practice may differ. The learning of a foreign language, even if it is not as formidable a task as some persons seem to consider, certainly does demand an intellectual effort, and one cannot expect anybody but the very few to be willing to take up more than the two or three essential ones. It is interesting to note, however, from the table that the question whether two or three Western main languages must be learnt does not seem to upset the tendency to learn other languages besides. It may be that very much excellent science is at present published in other languages; but as long as these languages are, and cannot but be, inaccessible to the majority of those who would otherwise have been potential readers, this body of knowledge does not exist to all intents and purposes.

Those who belong to a major language, and who perhaps have, or perhaps have not, taken the trouble to acquire a reading knowledge of two other languages, should show indulgence towards those who have been obliged to learn enough of a third one to be able to write it—which is something quite different. I have a personal reason for this appeal. Some years ago I, together with a Danish colleague, published a book (170 pages) in English, which was reviewed in *Nature*[2]. It was a very kind review, but the reviewer expressed his regrets that the English (which had, incidentally, been checked by two English colleagues) was not good enough. At my request the reviewer very kindly furnished me with a list of his grievances. They were, in all, twenty-eight, of which seven were misprints, two referred to a Latin word, one was rejected for being American, and four were new words we had to construct because no such word existed in English—they were all misunderstood, perhaps they were badly constructed. Three cases were disputable (usage accepted by the Concise Oxford Dictionary), and there remained eleven cases of more or less awkward usage. No expression was so awkward that it interfered with intelligibility.

I mention this at some length, not to give vent to any personal feelings against a deceased colleague, but because it is an excellent example of what should not be done. Nothing could be better calculated to scare people away from using the great languages than just this kind of purism. It may be maintained that French purism has destroyed French as a universal language. If English is to go the same way, the outlook for future scientists is very gloomy indeed.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 20

British Society for the History of Science (in the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. Gordon Manley: "Contributions to Instrumental Meteorology before 1800".

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Informal evening on "Ultrasonics in Industry". Talk by Mr. C. F. Brocklesby (with films and demonstrations).

Society of Chemical Industry, Pesticides Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. Carmichael: "Recent Advances in the Use of Insecticides in Animal Health".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. W. C. Price: "Spectroscopy in Science and Technology" (Inaugural Lecture).*

Manchester Literary and Philosophical Society (at the University, Manchester), at 5.45 p.m.—Prof. Clifford Holliday: "Anuradhapura, Sacred City of Ceylon" (Percival Lecture).

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Dr. D. J. Crisp: "The Changing Climate of Northern Europe".

Tuesday, February 21

Society of Chemical Industry, Agriculture Group (in the Large Chemistry Lecture Theatre, Royal College of Science (Imperial College), Imperial Institute Road, London, S.W.7), at 10.30 a.m.—Symposium on "Some Cultural and Chemical Aspects of Crop Production".

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. Kathleen Lonsdale, F.R.S.: "Crystals, Temporary and Permanent: (1) Ice".*

Scientific Film Association (in the Mezzanine Cinema, Shell-Mex House, Strand, London, W.C.2), at 6.30 p.m.—Mr. A. J. Speakman: "The Film and Work Study".

Oil and Colour Chemists' Association (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. H. T. Bone: "Instrumentation and Automatic Control with Applications to Resin and Varnish Manufacture".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. R. C. McIntyre: "Design of Low Landing Speed Aircraft".

Wednesday, February 22

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. W. F. Bewley: "The British Glasshouse Industry".

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m.—Mr. G. J. Chamberlin: "Kippers, Cocktails, Confectionery and Colour"; 5.15 p.m.—Prof. M. Richter (Berlin): "Colorimetric Work in Germany".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. L. C. King: "A Geomorphological Comparison between Eastern Brazil and Africa" (to be read by Dr. F. Dixey); Mr. C. Downie: "Microplankton from the Kimmeridge Clay".

Society of Chemical Industry (joint meeting of the Food and Corrosion Groups, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Control of Corrosion in the Dairy Industry".

Thursday, February 23

Royal Society (at Burlington House, Piccadilly, London, W.1) at 4.30 p.m.—Mr. C. H. Gallagher, Mr. J. D. Judah and Mr. K. R. Rees: "The Biochemistry of Copper Deficiency. 1: Enzymological Disturbances, Blood Chemistry and Excretion of Amino Acids. 2: Synthetic Processes"; Mr. J. Green: "Variation in the Hæmoglobin Content of *Daphnia*".

Institute of Refrigeration (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. H. Burley and Mr. E. J. Perry: "Modern Trends in Dairy Refrigeration".

Physical Society, Acoustics Group (at the National Hospital, Queen Square, London, W.C.1), at 5.30 p.m.—Dr. D. E. Broadbent: "Physiological and Psychological Effects of Noise".

Friday, February 24

Institute of Metals (at the University, Edgbaston, Birmingham 5), at 10.30 a.m.—Informal Discussion on "Furnace Refractories for the Use of the Non-Ferrous Metal Industries".

Institution of Mechanical Engineers, Industrial Administration and Engineering Production Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 2.30 and 5.30 p.m.—Discussion on "The Productivity Report on Industrial Engineering".

Field Studies Council (at Goldsmiths' Hall, Foster Lane, London, E.C.2), at 4.30 p.m.—Annual General Meeting. Prof. S. W. Wooldridge: "On Understanding a Piece of Country".

Institution of Electrical Engineers, Supply Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. F. Bianchi di Castelbianco: "The Crossing of the Messina Straits with 230-kV. Double-Circuit Overhead Transmission Line".

Royal Institute of Chemistry (at Norwood Technical College Knights Hill, West Norwood), at 7 p.m.—Dr. J. B. Firth: "The Chemist in the Detection of Crime".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. N. Tinbergen: "The Activation, Extinction and Interaction of Instinctive Urges"

Saturday, February 25

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. Marian W. Smith: "The Swaixwe—a Social Dance of the American Indians of the Pacific Coast" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Secretary (graduate, preferably between the ages of 35 and 45, with a general knowledge of the content, organization and administration of technical education in this country, and preferably with experience in industry)—The Acting Secretary, National Council for Technological Awards, Ministry of Education, Curzon Street, London, W.1 (February 22).

Assistant Experimental Officer (with G.C.E. advanced level in chemistry or biology and one other science subject and an interest in biochemistry; if over 22 a pass degree, higher national certificate or equivalent) in the Department of Scientific and Industrial Research, Food Investigation Low Temperature Research Station, Cambridge, to assist in studying the chemistry and microbiology of spoilage in poultry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G.29/6A (February 25).

Senior Lecturer (with a good honours degree, together with teaching experience, and preferably with industrial or research experience) in Inorganic Chemistry at the City College of Technology, Liverpool—Director of Education, 14 Sir Thomas Street, Liverpool 1 (February 25).

Lecturer in Organic Chemistry—The Principal, Royal Holloway College, Englefield Green, Surrey (February 27).

Senior Research Fellow (with an honours B.Sc. degree in chemistry or biochemistry and research experience) in the Department of Biological Chemistry—The Secretary, The University, Aberdeen (February 29).

Assistant Bacteriologist (science graduate) in the Regional Bacteriological Laboratory, Raigmore Hospital, Inverness—Secretary and Administrative Medical Officer, Office of the Northern Regional Hospital Board, Raigmore, Inverness (March 3).

Assistant Lecturer or Demonstrator in Pathology—The Registrar, The University, Manchester 13 (March 3).

Assistant Lecturer (with special qualifications in applied mathematics) in Mathematics—The Registrar, The University, Manchester 13 (March 3).

Deputy Librarian—The Registrar, The University, Sheffield (March 3).

Lecturer (preferably with a higher degree) in Physics—The Registrar, King's College, Strand, London, W.C.2 (March 9).

Simson Chair of Mathematics—Secretary of University Court, The University, Glasgow (March 9).

Lecturer or Assistant Lecturer in Mathematical Statistics—The Registrar, The University, Manchester (March 10).

Research Assistant (with a degree in biology or a closely allied subject, and preferably with experience in histology) in the Department of Biomechanics and Surgical Materials at the Country Section, Royal National Orthopaedic Hospital, Stanmore, Middlesex—The Dean, Institute of Orthopaedics, 234 Great Portland Street, London, W.1 (March 10).

Professor of Textile Technology in the University Alagappa Chettiar College of Technology, Guindy—The Registrar, University of Madras, Madras 5, India (March 12).

Chair of Physics—The Secretary, The University, Exeter (March 15).

Chemists (3) (with a good honours degree in chemistry, and for one of the posts at least 2–3 years research experience in organic chemistry) for work in a new research group being established in the University of Exeter for investigations of chemistry of tobacco smoke, with particular reference to its possible influence on incidence of cancer of the lung—The Vice-Chancellor, The University, Exeter (March 15).

Air Pollution Engineer (with a university degree in chemical technology or equivalent qualification and about twelve years experience in chemical engineering or allied activities) in the City Engineer's Department, Durban—Messrs. Webster, Steel and Co., 3 St. Helen's Place, Bishopsgate, London, E.C.3 (March 16).

Chair of Prehistoric European Archæology at the Institute of Archæology—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 21).

Chair of Veterinary Medicine—The Registrar and Secretary, The University, Bristol (March 23).

Chair of Philosophy—The Registrar, University College, Leicester (March 24)

Chair of Physical Chemistry at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, March 28).

HEAD (with high academic qualifications, considerable research experience and established administrative ability) OF THE BOTANICAL DIVISION of the Rubber Research Institute of Malaya, Kuala Lumpur—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (March 26).

DIRECTOR (with proved high scientific attainments, preferably in fields related to soils or crops, combined with administrative experience either as head or deputy in the organization and running of a research institute or university department) OF THE COCONUT RESEARCH INSTITUTE OF CEYLON—The Chairman, Coconut Research Board, Department of Agriculture, Peradeniya, Ceylon (March 31).

LECTURER (with a degree in mining engineering, or equivalent, from a university or university school of mines, and either operating or research experience in ore or mineral dressing) IN MINING ENGINEERING at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

SENIOR LECTURER (with a higher degree in psychology) IN PSYCHOLOGY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

ASSISTANT CONSERVATOR (with a university degree in forestry) OF FORESTS in Sierra Leone—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.61/15/04.

ASSISTANT LECTURER IN SOCIAL ANTHROPOLOGY—The Secretary, London School of Economics and Political Science, Houghton Street, London, W.C.2.

BIOCHEMIST in the newly equipped Clinical Research Laboratory—The House Governor, Royal Marsden Hospital, Fulham Road, London, S.W.3.

CHIEF MATERIALS ASSISTANT (under 40, with a wide experience of laboratory work on soils, bitumen, concrete and other building materials, and preferably with a B.Sc. degree or H.N.C. or other similar qualification in physics or engineering) in the Public Works Department, Kenya, to check and control all test results reported by soils, bitumen and building material laboratories, under the direction of the Chief Materials Engineer—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.112/7/036/CI.

LECTURER IN BOTANY (Assistant Grade B)—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

MASTER TO TEACH PHYSICS at least to advanced level together with some Mathematics—The Head Master, Westminster School, 17 Dean's Yard, London, S.W.1.

MEDICAL PHYSICIST (preferably with previous experience)—Group Secretary, War Memorial Hospital, Scunthorpe.

OPERATIONAL RESEARCH OFFICER (with a good university degree in mathematics, science, engineering or economics, and previous operational research experience) to study factors effecting productive efficiency throughout the Corporation—Head Office Personnel Officer, British European Airways, Keyline House, Ruislip, Middlesex.

PHYSICAL CHEMIST (with a first- or second-class honours degree or equivalent qualification in chemistry) at a Ministry of Supply Research and Development Establishment, Waltham Abbey, Essex, to study rheological properties of solid systems based on visco-elastic polymers and to assist in formulation of such polymers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.77/6A/AA.

RESEARCH ASSISTANT (female, with a degree in chemistry and an interest in the physical chemistry of biological systems)—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey.

RESEARCH PHYSICIST (with a good honours degree) to assist in research into the fundamental principles underlying the processing of textile fibres into yarns—The Secretary, The British Jute Trade Research Association, Kinnoull Road, Kingsway West, Dundee.

SENIOR LECTURER (with an honours degree in mathematics, and preferably with research experience) IN MATHEMATICS—The Principal, West Ham College of Technology, Romford Road, Stratford, London, E.15.

SENIOR LECTURER (with experience in some field of applied physics (for example: electronics, solid state physics, vacuum technology, applied heat)) IN THE PHYSICS DEPARTMENT—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

TECHNICAL ASSISTANT (with a pass degree or equivalent in chemistry, biochemistry or physiology) to assist in biochemical research into certain aspects of diabetes—Professor of Physiology, The Medical School, King's College, Newcastle-upon-Tyne 1.

CHAPMAN & HALL

RESONANCE IN ORGANIC CHEMISTRY

by

G. W. Wheland

(Professor of Chemistry, University of Chicago)

Size: 9½ in. × 6 in. 846 *pages* *Illustrated* 120*s. net*

This book is possibly the only current work dealing specifically with resonance theory in chemistry. It differs from the conventional treatment of organic chemistry in its explicit concern with the application of quantum mechanical methods to problems of molecular structure. At the same time, it differs from books on quantum mechanics in that its approach is uniformly chemical and, in particular, organic chemical.

HYDROGEN PEROXIDE

by

Walter C. Schumb **Charles N. Satterfield** **Ralph L. Wentworth**

(Respectively: Professor of Inorganic Chemistry; Assoc Professor of Chemical Engineering; Industrial Liaison Officer; at the Massachusetts Institute of Technology)

Size: 9½ in. × 6 *in.* 760 *pages* *Illustrated* 132*s. net*

This is the first comprehensive treatment, in book form, of the manufacture, properties, technology and uses of hydrogen peroxide. This valuable new monograph, with more than 2,500 literature references, offers scientists, engineers and all users of hydrogen peroxide, an authoritative and exhaustive survey of existing knowledge on a subject of ever-increasing importance.

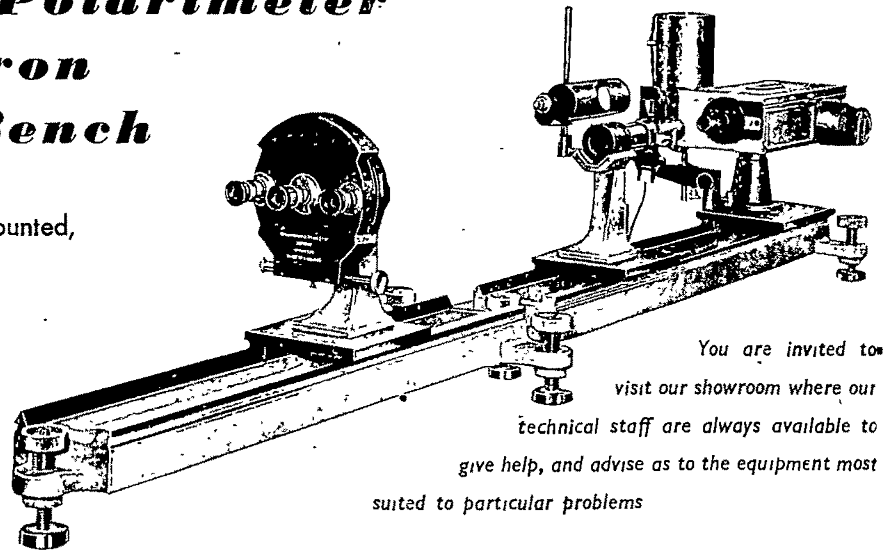
37 ESSEX STREET, LONDON, W.C.2

PRECISION B S INSTRUMENTS

Model A Polarimeter on cast iron Optical Bench

Monochromator can be mounted, as illustrated, when desired.

Suitable for the insertion of auxiliary apparatus between polariser and analyser.



You are invited to visit our showroom where our technical staff are always available to give help, and advise as to the equipment most suited to particular problems

EDUCATION AND THE RHODES TRUST

THE record of the first fifty years of the Rhodes Trust and the Rhodes Scholarships which has been compiled in connexion with the jubilee of the Trust* is intended primarily for domestic consumption by former Rhodes Scholars, to whom it is being presented. Informal and episodic and admirably produced, its composite authorship does not disturb the unity of the book but rather testifies to the unifying power of the ideal which men of such varied outlook, ability and temperament as Lord Elton, Sir Francis Wylie, Sir Carleton Allen and Frank Aydelotte (American Secretary during 1918–52) have sought to promote. It does not, indeed, claim to be a history of the Rhodes scholarships, still less of the Rhodes Trust. Lord Elton, writing of the Rhodes Trust, endeavours to provide the background against which the personal reminiscences of the Rhodes Scholars in Oxford by Sir Francis Wylie and Sir Carleton Allen, which constitute the core of the book, and Frank Aydelotte's account of the American Scholarships and their administration, may be read. Lord Elton's contribution, in particular, contains shrewd comments and observations on educational issues of the day. A foreword written by Mr. L. H. S. Amery, who died while the volume was in the press, rightly suggests that the story told in its pages has a close bearing on wider educational issues, even if it gives no convincing answer to the question: What did Cecil Rhodes hope to produce by his Foundation? There are, it is true, answers, in some measure, to two other questions noted by Mr. Amery: What has Rhodes's benefaction enabled Oxford to give to those for whom it was intended and to the world outside? And what has Oxford, as a University, itself gained from that benefaction? That those answers are incomplete adds to, rather than detracts from, the value of the book. For it is not only a readable and lively if informal historical record, but also a timely contribution to live issues in higher education to-day. It is timely for the sufficient reason that the record makes it quite clear that generations are required to judge the full effect of experiments in education.

Such a reminder is timely when Britain is faced with the imperative need to expand its system of technological and technical education. It is not always fully appreciated that there is no time to experiment with a technological university—if by that is meant that full expansion must wait until the lessons can be drawn years hence from the results of that experiment. The decision as to what form the expansion of technological education in Britain should take must be based on the abundance of existing experience, and the argument for a technological university rests, in part, on the possibility that a new departure in the British context might yield fresh experience and unexpected results. There is always room for variety in education, but the report on the Rhodes Trust, while testifying to that truth, is equally a warning against committing limited resources excessively to a new departure before we are clear where it will lead.

The warning is needed in other fields besides technological education, and there is another warning to be found in these pages. Even in these fifty years the setting of the Rhodes Trust and of the Rhodes Scholars has changed. Oxford is not to-day the Oxford that Cecil Rhodes knew. As Lord Elton points out, "in the Founder's day, the clamant demand for knowledge as such, the paramount emphasis upon research as the primary duty of a university, was virtually unknown. Mr. Rhodes pictured his Scholars drinking deep of the humanities and rubbing shoulders with their coevals in the College common-rooms and quadrangles rather than as enlarging the sum of human knowledge over a laboratory retort". While to-day the fervour for research is still increasing all over the world, the much wider social strata on which, with economic changes, Oxford now draws has made the University yet more unlike the University of fifty years ago.

These changes have set problems in the administration of the Trust; nor are they altogether avoidable. In deciding education policy which may shape educational institutions for decades ahead, care therefore should be taken to ensure flexibility. It is not merely that the needs of the society which the institutions exist to serve may change, that some functions may become obsolete, that new needs may arise and require service: the nature of society itself may change, and institutions admirably adapted to one form may consort ill with the new one. We need to keep room for manœuvre and for putting more ideas and methods to the proof, and to avoid committing irretrievably the nation's resources into one form which may either fail to fulfil its initial promise or, in unforeseen and changing circumstances, prove less suitable and efficient than was expected.

This is, of course, precisely the argument for the independent institution as the growing point of society in education, no less than in research. This record, moreover, shows the value of the independent and unofficial institution in another respect. The effect of the increasing place which research has come to hold in the life of the university has already been noted, and it has been hinted that this has raised problems for the Rhodes Trustees. Even in 1929, however, the relative advantages of honour schools and postgraduate research were being debated at a conference of members of the selection committees and university officials, most of whom held that Rhodes Scholars should continue to take the undergraduate course at Oxford, as the best and most characteristic teaching which Oxford offered. Most of them also agreed that the importance of higher degrees and research work as a method of education was largely over-estimated. Nevertheless, in his subsequent memorandum to selection committees, Lord Lothian made it clear that a growing proportion of the ablest men could not be expected to compete for Rhodes Scholarships unless adequate facilities for postgraduate study were developed at Oxford.

---

* The First Fifty Years of the Rhodes Trust and the Rhodes Scholarships, 1903–1953. Edited by Lord Elton. Pp. xiv+268+19 plates. (Oxford: Basil Blackwell, 1955.) 27s. 6d. net.

Seven years later, in 1936, when recommending the Trustees to contribute £100,000 to the projected University of Oxford Appeal, Lord Lothian pointed out that no university could keep in the front rank unless a considerable proportion of its leading figures were actively engaged in extending the limits of human knowledge, rather than in imparting to successive generations of students the body of learning which they themselves had inherited from their predecessors. In making this gift of £100,000, the Trustees expressed the wish that it should be used to support research in social studies with special reference to "the problems of modern government in the British Commonwealth and the American Republic". Oxford had indeed been chosen by Rhodes because he regarded the study of Greek culture and Roman law as invaluable for young men who were likely to be called upon to practise the art of government.

Education for management and administration and for the art of government was clearly in the mind of the founder of the Trust—or, as perhaps it might be better put to-day, education for leadership. The selection of Rhodes Scholars has obviously been guided by the desire to choose those best fitted by character and intelligence to develop as leaders of their generation in the various walks of life and progress most towards that end by the opportunities which Oxford offers. Nevertheless, there are two important points which any reading of this survey in such a context suggests need fuller consideration.

So far back as 1927, Lord Lothian had expressed doubt whether an increasing tendency then becoming apparent among Rhodes Scholars from the Commonwealth to study the sciences rather than the arts was an advantage from the point of view of Mr. Rhodes's larger ideals. The founder, he argued, had selected the University of Oxford largely because he believed that the type of education given there, with its outlook on the civilization of Greece and Rome, its interest in philosophy, history, law and political science, would develop in his Scholars those attitudes which would specially assist them in the discharge of public duties in after-life. It is not under-rating the value of a scientific education at Oxford or elsewhere to suggest that this point of view should be remembered in the current debates on general education and education for management and leadership.

Sir Carleton Allen makes a specific point in this connexion. He knows of no place where the use of the English language is more sedulously disciplined than at Oxford. "Looseness, verbosity or vulgarity of expression are of all things anathema, and it is, or ought to be, an axiom of tutorial instruction that bad style is bad thinking." If Rhodes Scholars take nothing else from Oxford, they will be in her debt, he suggests, if they have learned to weigh their words before committing them to speech or paper.

Oxford's special strength may well lie, as Sir Carleton suggests, more in its tutorial system than in its supervision of research, and even in the natural sciences, where the research technique of Oxford is most highly developed, there is danger that a Rhodes Scholar may become so tied to his laboratory that he is alienated from the more miscellaneous but educative activities of student life. We may accept, too, that the man who is living in college and working under a good tutor is more likely than the specialist to get the characteristic flavour of Oxford and enter into the main current of its life, and that not every Rhodes Scholar will profit more by postgraduate work than by a 'final honour school'. If, however, a scientific discipline fails to impart precisely that care in the use of the English language which Sir Carleton lays down as characteristic of Oxford, there is something wrong with the teaching of those disciplines. It is not that science is not worth study by the Rhodes Scholar, but that the teaching of science should be on a par with the teaching of those other disciplines in which Oxford has been pre-eminent.

This is an important point, for we cannot expect the Rhodes Scholar to take the place in the world of to-day and to-morrow that the founder of the Trust envisaged unless he is equipped to understand the forces which are moulding it and the way in which they work. An understanding of science and its method is as essential a part of the equipment of the administrator or statesman to-day as the ability to weigh his words and communicate his ideas clearly and concisely. It is also true that the Rhodes Scholars are unlikely to exert their full influence on the world of to-day unless a reasonable proportion of them enter the world of science; and this does not appear to be happening, at least on the evidence provided by the records and statistics collected by Sir Carleton Allen.

Among the Commonwealth Rhodes Scholars, the proportion studying sciences has increased from 54·2 per cent before the First World War to 68·1 per cent between 1918 and 1925, but fell to 35 per cent in 1954; among American Rhodes Scholars the corresponding figures are only 12·2, 14·7 and 16 per cent. While the roll includes such names as those of Dr. Wilder G. Penfield, Sir Howard Florey and Sir David Rivett, the analysis of vocations of former Rhodes Scholars reveals only six who pursued agriculture and animal husbandry, 46 chemists (chiefly industrial), 79 engineers, 19 foresters, 15 geologists and geophysicists, 171 medicals, 66 other scientists, mainly physicists, besides 3 anthropologists and one archæologist who could possibly be included under science, a total of 406 out of the 2,571 Scholars elected up to 1949 whose careers are recorded by Sir Carleton Allen. It does not, however, take account of the 138 scientists included in the 618 Scholars who adopted an academic vocation.

Sir Carleton Allen also notes that postgraduate work is attracting an increasing proportion of Rhodes Scholars, the percentage of those reading for research degrees ranging from 30 to 41 between 1947 and 1953, and of these nearly one-half are engaged in one or other of the natural sciences. Nevertheless, it is more than doubtful whether, however carefully the Rhodes Scholars continue to be selected, they will make in the future the powerful contribution to the national life of the countries from which they come or in which they elect to spend their professional life, unless something more than a fifth of them on average have studied the sciences. It would be fatal to that influence in an age in which nuclear physics is placing such immense possibilities for good or evil in the hands of men if the impression prevailed that, as a class, the Rhodes Scholar usually lacked first-hand acquaintance with the forces that are shaping the world.

Admittedly, science is not the only force involved, but it cannot be ignored and it can only be guided if understood. We need more than ever that influence upon the outlook on intellectual and moral problems which Rhodes Scholars have exercised upon all the professions they have taken up. That influence, derived essentially from Oxford, is described by Mr. L. H. S. Amery as one of the most important services rendered by the Rhodes Scholar; and he concedes, too, that the practical needs of the Rhodes Scholars have steadily reinforced the growing recognition of the importance of research, of the fact that a great university cannot live merely by transmitting an existing body of knowledge and ideas but must make its contribution to the body of knowledge. The Rhodes Scholars must therefore keep in the full stream of modern life and represent and interpret not merely the best traditions of the past and aspirations of the present but equally the forces that are shaping the future.

There is one point noted by Lord Elton in discussing the influence of the scholars and the scholarships which has its bearing on the problems of higher technological education and the general education of both the scientist and the arts graduate in Great Britain. Lord Elton believes that the care taken in selecting Rhodes Scholars for their possession of character as well as of intelligence makes the Rhodes scholarships an even more important influence for good in the life of a university. Until recent years, the tendency in our general scholarship system to concentrate exclusively on the possession of intellectual qualifications has been largely offset by the fact that a high proportion of those obtaining scholarships came from Public Schools, in which emphasis has always been laid upon the training of character. These schools no longer supply the same proportion either of 'open scholars' or of the general body of undergraduates, and at the same time the life of a university is also impoverished by a decrease in the numbers of those, adequately industrious and intelligent, but whose independent means enable them to take a more active part in the social and athletic life of college and university.

This is a trend of which due account should be taken in expanding the provision for higher technological education in Britain, and in our plans to meet the impending 'bulge' in university students in the 'sixties. We cannot rely entirely, even at Oxford, on the beneficial influence of the Rhodes Scholars. But at the least, this inspiring account of the translation into practice of a great ideal is a reminder of the importance of vision and flexibility where educational institutions are concerned, of the need to avoid hasty judgments and preconceived ideals, and of allowing for more ways than one for achieving our purpose before we take decisions which may affect the welfare and service of the State not merely to-day but for a generation or more to come. The Rhodes Trust and the Rhodes scholarships are a supreme demonstration of the truth of Sir Ernest Barker's words in "Age and Youth": "I had always felt that much of what was great and fine in the history of my country —much in its religious life, much in its system of education, much in its development overseas into a Commonwealth of free nations, much in its system of parties and in its general system of self-government—was ultimately based on my countrymen's habit of doing things together for themselves in voluntary co-operation".

FOOD PROBLEMS IN THE UNITED STATES

Handbook of Food and Agriculture

Edited by Fred C. Blanck. Pp. vii+1039. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1955.) 100s. net.

THIS is a remarkable book. It is a collection of twenty-six chapters, each by separate authors, of whom there are twenty-nine: it runs to more than a thousand pages of about five hundred words to a page, and it deals with almost every aspect of food production, processing, packing and delivery, especially with the last three items. The section on production is the lightest, consisting of four chapters only, dealing respectively with soils, soil fertility, soil microbiology and fertilizers, covering altogether less than a hundred and fifty pages. Within the limits of space thus imposed, the accounts are good and include most of the subjects recently investigated in America. There are few references to work done outside the United States: in the account of the fixation of nitrogen by leguminous plants, no mention is made of H. G. Thornton's classical investigations; and in describing composts, the need for adding a source of nitrogen such as calcium cyanamide to feed the bacteria and thereby hasten decomposition, which was demonstrated by H. B. Hutchinson and E. H. Richards at Rothamsted in 1921 and formed the basis of the 'Adco' patent, is attributed to an American investigator in 1948. Nor in the fertilizer section is any reference made to the Rothamsted experiments or to the need for proper statistical control of the design of the field experiments and the discussion of the results.

The book must be read, therefore, as principally a statement of American results, and from this point of view it is a mine of interesting and valuable information. Thanks to the friendly co-operation between the soil workers in Britain and in the United States, the material in the chapters on soil is pretty well known to experts in the former country. Some of the information on fertilizers, however, will be new to many readers. Soil conservation activities in the United States have raised the consumption of liming materials from 3·3 million tons a year in 1935 to 13·1 million tons in 1940 and 26·5 million tons in 1950. Prior to 1900, organic manures supplied more than 90 per cent of the nitrogen added to the soil; since 1950 they have supplied less than 4 per cent, the rest being from chemical fertilizers. These supply more than a million tons of nitrogen a year, much of it in the form of ammonium sulphate, but a large and increasing use is made of free ammonia, for which special appliances have been designed. Slow-acting nitrogenous fertilizers based on urea are coming into use, and promise to solve some of the grower's difficulties; it is interesting to note that for this purpose urea has to be imported. As in the United Kingdom, American farmers show a decided preference for mixed fertilizers over single ones; the general formula has changed in the same direction: prior to 1915 the ratio $N : P_2O_5 : K_2O$ was 1 : 4 : 1; it is now approximately 1 : 2½ : 2. There is a tendency also to use more concentrated fertilizer, but granulation is not as usual as in Britain. A very informative chapter on pest control agents includes some pages of constitutional formulæ of the more common organic substances used for this purpose and made on an increasingly large scale—a triumph of modern chemical technology. The need for these control agents is growing: the damage done annually in the United States by insects is roughly estimated at 4 thousand million dollars, by plant diseases at 3 thousand million dollars, and by weeds at more than is done by insects and all plant and animal diseases put together. The authors state that the apple grower "has to compete with 200 infectious diseases and 100 insect pests in order to produce a marketable crop"; it is not surprising the United States Department of Agriculture has a list of thirty thousand pesticidal formulations.

Most of the book is occupied by the processing, storage, packing and transport of foods; these chapters are a rich mine of interesting and sometimes intriguing information. Wheat is made into a number of different foods, in all of which it can be recognized. But maize can be used in making a surprising number of products of the most diverse character: foods for man and beast, antibiotics, cosmetics, chewing gum, explosives, rayon, tobacco, paper, soap, ice cream and various other things. The book ends with some useful chapters dealing respectively with control of quality in food, the disposal of food-plant wastes, and the use of chemicals in food. Altogether, it is an interesting volume.

But it is dear. Its price in Britain is £5—a reflexion, no doubt, of the high cost of production in the United States, but all the same hard on a British buyer. E. JOHN RUSSELL

THE EXTRA PHARMACOPŒIA

The Extra Pharmacopœia (Martindale)

Vol. 2. Twenty-third Edition in two volumes. Pp. xxxi+1501. (London: Pharmaceutical Press, 1955.) 57*s.* 6*d.*

THIS book, which is the latest reincarnation of the second volume of the famous work by Martindale and Westcott, contains a large amount of compact information. The two volumes of the twenty-third edition together contain more than 2,850 pages. The first edition was published in 1883 and contained only 313 pages, and the book grew slowly at first and then rapidly between 1900 and 1910. Since then it has grown at a fairly steady rate, but the interval between editions has increased from two years up to eleven or twelve, so that the amount of matter added with each edition has increased. It is a pity that the interval has grown so long, but the labour involved must be enormous.

In this Vol. 2 about 450 pages are devoted to analytical addenda to Vol. 1—the methods by which the pharmacists ensure that the drugs we use contain the proper ingredients and nothing more. Sections are devoted to *p*H, oxidation potentials, polarography, indicators, ion-exchange resins, chromatography, spectrophotometry, fluorimetry, the microbiological assay of vitamins, food analysis, water analysis, sterilization, disinfectants, radiotherapy, electrotherapy, nutrition, hæmatology, clinical biochemistry and various other topics which come within the wide range of subjects which the pharmacist understands.

The section on the nomenclature of organic compounds has developed gradually through several editions, and will now be very valuable to those who have to try to understand organic structures without being organic chemists. It is a pity, however, that there seems to be no clue to the meanings of the prefixes such as *cis* and *meso* mentioned on p. 768, and surely *nor* means "N ohne radikal" and not "the next lower homologue".

There is a stimulating section on what the Americans call SAR (structure action relationships), but sulphanilamide was not the first useful drug the action of which was traced to its close resemblance to a natural metabolite (p. 780). The theory that some drugs act in this way had been widely discussed in connexion with eserine, atropine, ephedrine and other drugs for many years before it was applied to sulphanilamide.

Enough has perhaps been said in this review to show that the book not only gives much information, but also provokes thought. It is a worthy successor to a long line of famous forerunners.

J. H. GADDUM

ANTHROPOMETRY AND HUMAN ENGINEERING

Anthropometry and Human Engineering

A Symposium on Anthropometry, Human Engineering and Related Subjects conducted by the AGARD Aeromedical Panel on 3 and 4 May 1954 in Scheveningen, The Netherlands. (AGARDograph No. 5.) Pp. iv+123+3 plates. (London: Butterworths Scientific Publications, 1955; published for A.G.A.R.D.) 21*s.*; 3 dollars.

THIS publication originated from a symposium conducted by the Aeromedical Panel of the Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization, and shows a well-defined grouping of related papers. The various approaches by the different authors add considerable interest to what could be a heavy subject. Its scope is wide, and it should be of interest to the aeronautical engineer and applied psychologist. Indeed, the latter may be impressed by the scope and importance of the work in his field introduced in this volume. Basic concepts of instrument display and design are explained in a lucid manner. It is apparent that controversial issues are developing rapidly, and there is a great need for more fundamental research along these lines. In this respect, the topics introduced by the various specialists in aviation medicine and psychology point out shrewdly the future trends. Anyone concerned with instrument design outside the aviation industry might well take heed of these aspects of human engineering which have a universal application.

The papers devoted to anthropometry indicate the impetus given to statistical work of this nature by aviation in general. In the man/aircraft combination, the work space is critical, and approximately one-third of the book is devoted to this subject, which includes a large-scale survey of body measurements carried out in the French Air Force. Research and applications carried out for the Royal Air Force are summarized in an excellent manner and point out to the engineer his responsibility in this field.

The third part of the book, dealing with related subjects, is essentially the general medical application of the previous concepts to aviation. For example, a paper on somatotyping by P. M. van Wulfften Palthe (Netherlands) usefully supplements the French statistical survey. It is suggested that anthropometric studies may be linked with psychological profiles drawn up by air-crew selection boards according to the principles developed by Kretschmer and Sheldon. Altogether, the book should arouse wide interest and appeal to many not directly concerned with aviation. F. LATHAM

SERVO-MECHANISMS AND CONTROL SYSTEMS

Engineering Cybernetics

By H. S. Tsien. Pp. xii+289. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 46*s*. 6*d*.

WHEN a new book arrives on my desk nowadays, I am always hoping that it may not be yet another book on servo-mechanisms and control. Usually it is the mixture as before: a few hackneyed phrases to be written about the ever-growing need for more automatic control in industrial processes; the need for a sound mathematical background; the wide interpretations of the concept of feedback; the accelerated growth of a new science, etc. For the market is flooded with books on the subject. When I saw the title of the volume under notice, "Engineering Cybernetics", my fears were roused, and I must admit to approaching the work with a sense of irritation and in an antagonistic mood. The author has done himself a great disservice in choosing such a misleading means of introducing his book; for a glance at the contents and the preface shows it to be confined strictly to the field of mechanism, making no reference to biological matters or sociological affairs.

But if the title was a frightening thing, the contents were a soothing balm—for this book turned out not to be the same old medicine. Regarded strictly as a text upon the theory of servo-mechanisms and control systems, and nothing else, it is honest and excellent. A great deal of material will be found which is not readily available, to my knowledge, in any other collected form. It can be recommended to the attention of fairly advanced students of servo-mechanism theory, feedback and control processes. In his preface the author excuses the title on the grounds that it denotes ". . . an engineering *science*. whereas servo-mechanism engineering is an engineering *practice* [italics his]. . . . No gadget is mentioned". But I protest: gadgets are mentioned. The book is full of them—diagrams and sketches of springs and dashpots, amplifiers and air-foils, relays and rockets; and a good thing too, for such intellectual prudery is quite out of place. Further, one excellent point of this volume is the great number of fully worked examples—really practical ones.

The author has succeeded well in presenting the essential mathematical techniques, methods and concepts, with explanations and illustrations drawn from a great variety of engineering mechanisms. The introductory sections perhaps serve little purpose, being bare facts about Laplace transforms, lists of operations, and rapid surveys of the mathematical elements; this is a fault which seems very common in many American text-books of this type. Either the reader must know his elements already or he must study them seriously, and at laborious length; he will gather little understanding from the sort of distillations so frequently seen. But this book very soon gets down to work. After a few chapters presenting what is by now the classical treatment of feedback mechanisms, more modern material is introduced. Systems with several controlled quantities are studied, with their interactions; and the need for new stability criteria is considered, with representation of such system behaviour by transfer-function matrices. A small criticism is that several electrical engineering terms, such as 'carrier', 'filter', are used without explanation. Would not a few words help mechanical engineers?

Systems having statistical inputs are taken next, after a good introduction to random process theory: averaging, correlation, power spectra, moments. Then relay servos are treated, their stability being examined by a modification of the well-known Nyquist criterion. This continuity of concept, with extension as proves necessary, is a most commendable policy adopted here. The student can hang on to reality a long while in terms of his existing mental images; and it becomes very clear when, and why, such images fail utterly and must be abandoned.

The work continues with the general properties of non-linear systems, and then with systems having variable coefficients, at which point the classical transform approach must be abandoned. Later chapters deal with the design of specific systems by perturbation theory; here, almost the entire work centres around one class of practical problem—the design of guided missiles to follow prescribed trajectories, or to seek a prescribed target—and the author reveals his own specialization. This problem is carried to great lengths, and includes allowance for the effects of atmospheric variations, for missile manufacture tolerances, etc. Both analysis and synthesis are studied.

There is a good deal of valuable descriptive material, besides the formal mathematics, in this book, giving some notion of purpose, of design difficulties, reasons for choice of methods and other matters so commonly omitted from such books—perhaps not being understood by the theoreticians writing them. But I would beg the author to change the title before a second edition. COLIN CHERRY

Gas Dynamics of Cosmic Clouds

A Symposium held at Cambridge, England, July 6–11, 1953. Edited by H. C. van de Hulst and J. M. Burgers. (International Union of Theoretical and Applied Mechanics and International Astronomical Union. I.A.U. Symposium Series—No. 2.) Pp. xii+247+12 plates. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1955.) 19 Dutch florins; 38*s*.

THE forty-four chapters in this book are mainly amended texts of papers and edited versions of discussions which took place at a symposium in Cambridge two years ago, and they were up to date in the summer of 1954. The meeting was the second of its kind, the first having been held in Paris in 1949. The report of the 1949 meeting, published under the title "Problems of Cosmical Aerodynamics" (Dayton, Ohio: Central Air Documents Office, 1951), gave the impression that the dynamics of cosmic clouds was a well-understood subject and that, for example, one needed only conventional turbulence theory, correctly applied, to explain the spiral structure of our galaxy and the motion of interstellar material.

The present report is quite different. There are many problems left after all. To take a few: Has our galaxy got spiral or circular arms and can present methods of observation ever tell us unambiguously? Do interstellar clouds sometimes condense to form new bright stars? If so, what happens to their angular momentum? Does uneven heating by these stars cause the irregular motion of the gas clouds? Do the clouds really move at Mach five, or even ten? What kind of theory applies to this type of turbulence?

The aerodynamicists at the symposium tried to help with reports of theoretical and practical studies, but contact was not really made: the phenomena to be explained are still a little too complex. However, the book makes stimulating reading and contains some very fine pictures. Even the reports of the discussions are worth looking at, for that is where many of the best remarks were made.

F. D. Kahn

Papirová Chromatografie

Edited by Dr. I. M. Hais and Dr. K. Macek. Pp. 720+10 plates. (Praha: Nakladatelstvi Československe Akademie Věd, 1954.) Cena brož, 136 Kčs.; vaz, 142 Kčs.

AS this book is written in the Czech language and is evidently intended mainly for workers in Czechoslovakia, any detailed comments would not be of interest to most readers of these columns; but it may be pointed out that the book provides Czech workers with a guide to all aspects of paper chromatography that is as useful as any which has been published outside that country. Among many valuable features are the detailed discussions of the applications of paper chromatography in structural studies of proteins and polysaccharides and of the applications of polarographic methods in quantitative work, topics which have not always received the attention they deserve in the books on chromatography.

The bibliography contains well over four thousand references and covers the literature up to 1953. As the title of each reference is given in full in its original language, this bibliography is of universal value and is probably the best source for Czech, Hungarian and Russian references. Another feature of general interest is the systematic list of a large number of reagents for detecting substances on chromatograms and of buffer systems used in paper electrophoresis. These directions can be fairly well followed even without a knowledge of Czech. It is to be hoped that copies of this treatise will be made available at least to the larger science libraries in countries outside Czechoslovakia.

R. Consden

Elementary Introduction to Molecular Spectra

By Børge Bak. Pp. x+126. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1954.) 9 Dutch florins; 18*s*.

A BOOK on molecular spectra as concise as this one deserves serious consideration. Excellent monographs which treat in detail of various aspects of the subject exist, and their number is added to year by year, but there remains a real need for a balanced introductory book to give the range and feel of the subject. The author has been bold enough to attempt this in the limit of 125 pages.

The result is not entirely satisfactory. Experimental matters are dismissed so superficially that the reader will scarcely form any useful idea of what the techniques are like, and he is never made to come to grips with a spectrum, so that the problems of analysis must remain unreal. There is a discussion (pp. 24–58) of the theoretical basis of the subject which occupies a disproportionately large space, but which will yet be of small help to a beginner. The emphasis, too, will not meet with acceptance everywhere; this is laid on the measurement of wavelength, and there is little talk of intensities. Justice is scarcely done to the vast body of work on quantitative ultra-violet absorption spectroscopy.

The book was prompted by a sound idea, and there is some good stuff in it—good enough, indeed, to make one hopeful that a revised edition will approximate more closely to what is wanted. The price is high: the language sometimes distinctly odd.

R. F. Barrow

Introduction to Theoretical Mechanics

By Prof. Robert A. Becker. (International Series in Pure and Applied Physics.) Pp. xiii+420. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 57*s*. 6*d*.

THIS book provides a straightforward and extremely competent introduction to the subject of theoretical mechanics. It may be said roughly to cover the three years of an honours physics degree-course in Britain; it starts with a chapter mainly devoted to vector analysis, and leads, through the usual topics in mechanics, to subjects such as accelerated reference systems, motion of a rigid body in three dimensions, generalized co-ordinates and vibrating systems.

It is definitely a work for physicists. The physics of each problem is clearly stated, and the mathematics introduced is shown to be the most suitable for the purpose concerned; there is no mathematics for mathematics' sake. The practical nature of the book is emphasized by the provision of problems at the end of each chapter; these are carefully chosen to provide all grades of difficulty so that both the average and the good student can test their abilities on them. Altogether, the book can be recommended as a reliable, workmanlike and carefully presented introduction to theoretical mechanics.

MARINE SCIENCE IN THE PACIFIC AREA

THE growing needs of marine research have brought to the United Nations Educational, Scientific and Cultural Organization many appeals for help from a wide range of projects, and the Director-General has felt the need for an advisory committee. Having received the necessary authority from the General Conference of 1954, he discussed the usefulness of such a proposal with a representative group of oceanographers meeting in 1955 after the Food and Agriculture Organization meetings in Rome, and after consulting that body and the International Council of Scientific Unions, he nominated an Interim Advisory Committee, with nine members and provision for regular changes in membership. Clear emphasis was given to the need for good working relations with the United Nations and its Specialized Agencies, and with the international scientific unions and regional bodies which are concerned with oceanographic and fishery research.

The Interim Committee met for the first time during October 24–25 and, on the invitation of the Japanese Government, the meeting was held in the International House of Japan in Tokyo. Symposia on oceanic circulation bearing on the biological resources of the Pacific Ocean, oceanographic instruments and exchange of information were held just before the meeting, and these followed a regional gathering of representatives of marine laboratories and the sixth session of the Indo-Pacific Fisheries Council.

The Advisory Committee started with a general discussion of trends and progress in marine research; it is not easy to summarize this without the full record, but some of the main features can be outlined. It was emphasized that there is still plenty of room for exploratory and descriptive work, especially in the Indian and South Pacific Oceans; but there was also clear insistence that much more than this is needed before the scientific studies can be applied successfully to the practical problems. It was emphasized that the problems are now of such a calibre that they need the attention of physicists, mathematicians, chemists, biologists and geologists who have proved outstanding in their own fields, and it was considered that applications of recent advances in these sciences to the study of the oceans have already proved sufficiently rewarding to interest specialists in applying their ideas to the ocean.

In physical oceanography new techniques and the methods of mathematical physics are beginning to revolutionize our understanding of ocean currents and waves. In marine chemistry such advanced techniques as mass spectroscopy, radiochemistry, emission spectroscopy, chromatography and biological assay are adding fresh significance to studies of substances present in very small concentrations and doing much to further the study of biogeochemical cycles. In biology new applications of genetics, biochemistry, population dynamics, physiology and bacteriology have furthered problems of great importance in the sea, and it seems very desirable that they should go hand in hand with future work on taxonomy, life-histories, morphology, zoo-geography and ecology. There was, however, some feeling that progress in marine research might suffer if the detailed studies, especially some of those using marine animals, are made without keeping the wider problems of the sea, particularly those of the deep ocean, in mind. In submarine geology the techniques of geophysical exploration and the latest methods of physical and chemical analysis would have to be used, as well as echo sounders and the older methods, to study the morphology of the sea floor and the character of the sediments.

There was some general discussion on the kind of laboratory needed for marine research. No one seemed to have much enthusiasm for an international laboratory entirely dependent on contributions from a number of countries. One of the objections was that marine research cannot be planned so nicely that each country would feel that its own interests and problems were receiving a fair share of attention. The difficulties might be less if the programme included the short-term examination of a number of immediate problems, but it seemed very doubtful whether the atmosphere of a joint laboratory, which had to justify itself continually to a joint administration, could be conducive to long-term research. Even in fisheries research, where knowledge of the life-histories, growth-rates and natural fluctuations in numbers of the principal food fishes is of obvious importance, joint ownership had not proved itself very sympathetic to a systematic approach.

There seemed to be a general feeling that support from private funds was conducive to stability and freedom for research, and that there were real advantages in making a relatively modest start centred on some local enthusiasm, emphasizing one aspect, probably marine biology, with later expansion into the other fields as additional funds became available for staff, ships and shore facilities.

For the more developed countries, the Committee considered that progress depends to a large extent on national centres for the marine sciences, at least partly supported by government funds. It was maintained that recent experience has shown that such centres should include men with special training and interests in applied mathematics, theoretical and experimental physics and geophysics, chemistry (geochemistry, biochemistry and analytical chemistry), geology, meteorology and biology (both experimental and ecological). Although the growth and outlook of a new laboratory depend to a large extent on personalities and local conditions, it seems essential to employ more than a certain number of permanent scientists (probably about ten) and to provide for adequate support in facilities and technically trained assistance. There was a general feeling that the research centre should be closely associated with a university.

The need for better facilities for the study of the deep ocean was specially emphasized, and although fairly serious difficulties are foreseen, a study of the feasibility of operating an international research vessel, to work primarily in little-explored areas, was considered well worth while. It was argued that the marine sciences are a natural and invigorating field for international collaboration, and that there is much in the study of the seas and marine animals to enrich human life culturally as well as economically.

Although it was not the business of the Interim Committee to decide the position of a Unesco Advisory Committee on Marine Sciences in relation to other organizations, particularly the International Council of Scientific Unions and the Food and Agriculture Organization, the question was often mentioned and there seemed to be a general feeling that the new committee would do useful work without wasteful overlapping. None of the scientists seemed to think a precise definition was needed, since each authority must obviously interest itself in the work and aims of the others while arranging its own meetings, grants and other activities with its own primary object in mind. The Food and Agriculture Organization has a primary duty to see that the best practical use is made of new and established methods and knowledge to find more fish and improve the supply, and to achieve this it must further education in the less-developed countries and support research in more-advanced countries to find improved techniques and a more effective understanding of the basic biological and physical processes. The International Council of Scientific Unions is concerned primarily with the development of the science; and although it is interested in seeing that all countries share in new developments and advantages, it must concentrate on invigorating the efforts of the most successful scientists. Unesco also has to encourage the new advances as, for example, by its generous treatment of the scientific unions; but its primary concern is to spread the science and its cultural advantages as widely as possible, taking special care of the less-developed countries.

The need to ensure that the relatively small international funds available for furthering marine research are used most efficiently was always in the forefront of the deliberations. The expense of administration and travel was lamented, but the importance of using them as energetically as possible to communicate enthusiasm, ideas and results was fully recognized. There can be no doubt of the value of the meetings in Tokyo. There was a good representation of Japanese scientists, a fair number of representatives from other marine laboratories in the Far East and a few American and European scientists, including representatives of the U.S.S.R.

Marine Science in Japan

The International Directory of Oceanographers, published by the Allan Hancock Foundation, lists only 129 names for Japan as against 195 for the United Kingdom; but in view of the number of laboratories and ships devoted to marine research in Japan, it seems likely that a rather different method of selecting names was used. Among the research institutions are the Japanese Hydrographic Office, under the Maritime Safety Board, seven regional fishery laboratories, the Central Meteorological Office and its four subordinate marine observatories, the Tokyo University of Fisheries, the Disaster Prevention Research Institute in Kyoto University, the Transportation Technical Research Institute and Whale Research Institute, and a number of university faculties devoted to fisheries and geophysics. This is by no means a complete list, since active research is also being carried on in laboratories devoted to basic sciences such as the Institute of Chemical Research, Kyoto University, and many other university departments. They are assisted by eighty ships, not counting vessels less than 20 tons, and although these are not entirely devoted to research they are actively engaged fully or part time in oceanography.

Such exceptional interest in the sea can be explained only by Japan's need to use marine resources to the full, and to take the most effective safety measures she can against the hazards of the typhoons and submarine earthquakes by which she is continually threatened.

Much of the work in marine physics has been related to the needs of navigation, meteorology, coastal engineering and the fisheries. The Japanese say they made their first sounding in 1872; but they have now very extensive programmes of coastal and oceanic surveys being made with the most modern methods. One of the most detailed surveys, of the strait between Honshu and Hokkaido, was made with the help of a portable set of Decca Navigational Aid, and it is claimed that a horizontal accuracy of ± 10 metres was obtained as far off as fifty miles from the stations. They have made extensive studies of the marine sediments, and have located several coal- and oil-fields on the continental shelf. Tidal observations have been made at more than a thousand places, and a new 42-component Légé tide-predicting machine is being installed. Particular attention is paid to the tidal streams, and a number of types of ingenious continuously recording meters are in regular use. Wave recorders are being used for studies of coast erosion, and tide recorders for research on seismic surges (tsunami) and storm surges (takashio). The marine meteorological research is primarily aimed at better understanding of the processes of energy exchange between ocean and atmosphere, and prediction of the water temperature; but the Central Meteorological Observatory has biologists and chemists as well as physicists in its oceanographic section, and initiates studies of the distribution of microplankton and macroplankton in relation to the water masses as well as variation of sea conditions, current boundaries, etc.

The fisheries research is aimed primarily at finding and improving the exploitation of fishing grounds and attempting to foresee fluctuations in distribution and numbers of mackerel, sardine, squid, herring, salmon, shipjack, tunas and whales. The work includes extensive ecological surveys of spawning and nursery grounds, and detailed studies to improve the understanding of variations in the principal currents, particularly the Kuroshio and Oyashio. It includes research cruises to the Bering Sea and more than half-way across the Pacific Ocean.

As in other countries, there is no obvious or logical division between the basic and applied research; but there seems to be a tendency for the initiative in the basic work to be with the universities, though they do not lack active collaboration from the government and regional laboratories devoted to hydrographic, meteorological and fisheries research. In marine physics there are energetic studies of wave generation and propagation, beach currents and shore-line changes, and a co-operative programme between the oceanographers and the Shipbuilding Research Association has recently been commenced. Forecasting of waves and swell is being studied and special attention paid to conditions of dangerous wave interference associated with typhoons. Theoretical and observational research on long waves, seismic and storm surges includes studies of the effects of dispersion, reflexion and refraction. Natural oscillations in lakes, bays and harbours are being investigated in connexion with harbour construction. Basic studies are being made of tidal oscillations, with particular attention to conditions in rivers, straits and shallow seas. A start has been made with studies of turbulence associated with the streams. Some experience has been gained in the use of electronic analogues. Statistical studies at the Earthquake Research Institute show that there is a tendency for the monthly mean sea-level to drop sharply before the large earthquakes.

Theoretical work on oceanic circulation presents many difficulties due to lack of information about actual velocities and mixing processes, and to the rapidly increasing complexity of the reasoning as the basic assumptions are made more and more realistic. The output of the Japanese workers in this field, largely owing to the influence of Prof. Hidaka, is enough to set ideas and conclusions running ahead of the observations and experiments. Marine research in Japan is likely to become remarkably productive if the theoretical workers are more actively helped and invigorated by the physicists, engineers and ships. There is a good measure of co-operation, but the practical facilities voted for attacks on obvious practical problems have to be devoted largely to methods which have been proved. This often means that the theoretical workers have to spend too long with pen and paper before they can put new ideas to work, and have their work stimulated, intensified and improved by practice and closer inquiry. This is a universal problem, but anyone attempting to survey marine science in Japan cannot fail to be impressed by the great wealth of observations, some of which have to be dealt with in fairly general terms, and by a similar wealth of theoretical work, some of which has to seek rather hard for the measurements that it believes most significant. The Japanese scientists lose no opportunity of checking measurements with hydrodynamical theory, and are well aware of the need to devote as much of the practical effort as possible to basic studies; but they might be able to do more if the responsibilities and burden of some of the practical requirements were shared by academic and technical workers in a laboratory in which both were well represented.

Some twenty Japanese scientists are making active contributions to the chemistry of the sea, including the development of new analytical methods and studies of variations in oxygen, carbon dioxide, nitrogen, phosphorus and other nutrients in relation to productivity, water movements and sediments. Attention is being paid to the elements in minor concentrations and to the geochemical implications of the work. Measurements of radioactivity near Bikini atoll have been used for studies of diffusion.

Japan has twenty marine biological stations, each with a staff of two to five full-time research workers as well as technical assistants and facilities for working in coastal waters. They lie between 33° and 43° N. over a very wide range of exposure and water conditions. In some the investigations are mainly physiological, without much immediate application to ecological and oceanographic problems. The local faunas are described, though not as completely as for some European laboratories. For work in the open ocean they rely on co-operation from the hydrographic, meteorological and fisheries laboratories, and active work is being done on productivity, indicator species, and the general character of regional faunas in relation to oceanographic factors. They emphasize the need for more taxonomic studies.

The Japanese instrument makers arranged an exhibition in connexion with the Unesco meetings, and it was apparent that they are keeping pace with new developments in marine research.

The International House of Japan was an ideal house for the meetings. The lecture hall will seat two hundred, and the dining hall and adjacent lounge could be combined to accommodate about the same number. There are forty-two bedrooms, single and double, and the service and meals were excellent. It is a non-profit organization, made possible by £100,000 collected in Japan and a grant of £125,000 capital expenditure and £25,000 a year for the first five years from the Rockefeller Foundation. It was formally opened in June 1955, and its activities aim primarily at promoting and sponsoring the international exchange and co-operation of intellectual leaders and creative artists, though some of its programmes are planned for students and the general public. The Japanese writer and lawyer Shigeharu Matsumoto is its managing director.

G. E. R. Deacon

RESISTANCE OF INSECTS TO INSECTICIDES

On January 9 the Association of Applied Biologists and the Society of Chemical Industry held a joint symposium in London on the subject of the resistance of insects to insecticides. The morning session was devoted to a discussion of the changes in resistance that can occur naturally before any kind of selection has occurred. The afternoon session was chiefly concerned with a discussion of the resistance that may develop following the use of insecticides.

The first paper, by C. Potter, dealt with the variations in resistance to insecticides that normally occur throughout the life-cycle of an insect and of the effect that differences in nutrition may have on resistance. It was pointed out that, in practice, insecticides are usually applied to kill a particular instar of a pest and it is important to choose the most susceptible instar for attack. Furthermore, since there can be variation of resistance with the age of the instar, detailed knowledge of the extent of these changes is desirable if control measures are to be put on a rational basis. Examples were then given to show the extent of the changes in resistance to insecticides that can occur throughout the life-cycle of an insect and also those that can occur during the development of a single instar. The changes throughout the life-cycle may be large; in one example quoted, it was more than 250 times. Smaller changes are found to occur within the instar, but even these can be appreciable, an example of a difference of more than sixteen times being given.

The examples given by Dr. Potter served to show that the extent and direction of the changes in resistance depend on the insecticide used, the species of insect and the conditions of treatment. It follows from this that not only may the absolute toxicity of any one insecticide differ with the stage of development, but also that the relative toxicity of any two insecticides is likely to differ also. There appears to be no information on the reasons for the differences in resistance between instars, and they are likely to be complex. Differences in resistance within an instar have been correlated with morphological and physiological changes that occur during its development, but these changes are not necessarily the cause of the differences. Examples were given to prove that the diet of the insect may affect its resistance to insecticide. This was shown to happen both by changing the constitution of artificial diets and by changing the host plants of insects that feed on living plants. The amount of food administered and the period when it was administered were also shown to affect resistance.

A. H. McIntosh then discussed the effect of temperature on the toxicity of insecticides. He stated that a change in the temperature at which insects are kept after treatment with poison nearly always affects the kill. If the kill increases with temperature, the temperature coefficient of kill is positive, and vice versa. In contact tests on grain beetles, the size of the temperature coefficient depends on the particle size used if the poison is a solid. If the temperature coefficient is negative, it is always bigger for colloid than for crystals; this happens with DDT and some of its analogues, rotenone and endrin. But if the temperature coefficient is positive, it may be bigger for colloid than for crystals, as with dieldrin, or bigger for crystals than colloid, as with 2-bromomercurithiophen.

The time elapsing between treatment of insects and counts of kill may sometimes affect the size and sign of the temperature coefficient. Thus, the temperature coefficient of dieldrin by injection into mealworms did not change as time passed (one to four days); but with rotenone the coefficient was negative if counts of kill were made up to about a day and a half after treatment, and after this it was positive. At the higher temperature, the percentage kill increased as time passed, but at the lower temperature the insects recovered from the effects of rotenone. The size and sign of the temperature coefficient may also depend on the dose, the method of application, the insect species and the range of temperatures used. The most that can be said about any one poison is that its temperature coefficient is usually positive or negative, as the case may be. Differences in temperature are certainly one cause of differences in both relative and absolute toxicities found by different workers.

K. F. Goodwin-Bailey then read a paper on behalf of J. M. Holborn on the susceptibility to insecticides of laboratory cultures of an insect species. The results of tests of the comparative resistance of strains of *Tribolium castaneum* (the rust-red flour beetle) and of strains of *Calandra granaria* (the granary weevil) were described. None of these strains had been exposed previously to insecticides, yet they showed consistent differences in resistance to the test poisons. A laboratory strain of *C. granaria* was found to be between three and a half and six and a half times as susceptible to pyrethrum powders as a wild strain. There was little difference in susceptibility when pyrethrins synergized with piperonyl butoxide were used. Several strains of *T. castaneum* developed from cultures from different laboratories were tested against γ-BHC, the pyrethrins and the pyrethrins synergized with piperonyl butoxide. The strain showed marked differences in susceptibility to γ-BHC and the pyrethrins, but the differences were less marked with the synergized pyrethrins.

The most resistant strain was four times as resistant to γ-BHC and three times as resistant to the pyrethrins as the least resistant strain. There is evidence that these natural differences were inherited through at least six generations. The differences in susceptibility found are thought to be due to differences in vigour. The results also show that the factor of synergism can differ greatly with the different strains. With the species examined, the synergist appears to be most effective against the most resistant strains, thus tending to diminish the differences found with the pyrethrins alone. The data presented in this paper provide evidence that considerable differences in resistance to insecticides can exist between strains of the same species, before any treatment with a poison has taken place; that is, that insecticide resistance is not always acquired by selection.

The first paper in the afternoon was read by J. R. Busvine, who discussed the occurrence and status of insecticide-resistant strains. He listed twenty-one species recorded since 1940 as having insecticide-resistant strains in the field. Only those records were listed which at the same time were substantiated with good supporting evidence for the existence of insecticide resistance. The criteria to be adopted in judging whether or not a resistant strain had been produced in the field were then discussed, and it was pointed out that the factors of natural high resistance, faulty insecticide or inefficient application, the elimination of parasites and predators and natural fluctuations in the insect population, should first be excluded. These factors make the field assessment of resistance difficult, and it should therefore be confirmed in the laboratory by a quantitative comparison with insects of the same species that have not been exposed to an insecticide.

The necessity for adequate standardization of the method of assessment of resistance was stressed, since errors can occur due to lack of standardization of the insect material, and different results may be given by varying the method of test. In general, high resistance is associated with flat probit/regression lines. The probit lines for resistant strains are nearly always flatter than for normal strains. Where two techniques of measurement are used, one may show a bigger difference between resistant and normal than the other; it generally occurs that the technique showing the bigger difference has the flatter probit line.

Dr. Busvine then considered the types of resistance that occur and concluded that the more important forms of resistance which result in the failure of control measures are characteristically specific to one type of insecticide. The grouping of the insecticides into types on this basis may indicate that they have a similar mode of action. The biochemical basis of resistance has been studied by some workers, and it has been shown that resistant strains have an increased capacity to detoxify DDT, although this alone is not sufficient to account for the degree of resistance that occurs. It was pointed out that there is some evidence of increased metabolism of the insecticide with strains resistant to γ-BHC, chlordane and toxaphene. Studies on the genetical bases of resistance have yielded very conflicting results, and there appears to be no general agreement. Dr. Busvine ended his talk with a plea for further research on this subject.

The next speaker, F. R. Bradbury, then gave a paper on the absorption and metabolism of benzene hexachloride in normal and resistant houseflies. The pick-up and absorption of vapours of γ-BHC and of its non-toxic α-, β- and δ-isomers by the housefly *Musca domestica* have been studied by confining susceptible and resistant strains over treated filter papers; labelling with carbon-14 and chlorine-36 has facilitated analysis. The general picture of resistance to γ-BHC deduced from the data broadly parallels that currently held for DDT. Resistant flies pick up and absorb less poison and perform a more rapid conversion to excretable metabolites with both the toxic and non-toxic isomers of BHC and, probably, there are differences in the distribution of the poison in the bodies of the susceptible and resistant strains. Resistant strains also convert a greater percentage of the absorbed dose in the earlier stages of storage.

By reversed-phase chromatography it has been established that the carbon tetrachloride extracts of flies treated with γ- and δ-BHC contain mainly unchanged BHC. No dehydrochlorination products have been detected in these extracts, and evidence that metabolism is accompanied by dechlorination was presented. The problem of the identification of the metabolic products is complex. In the metabolism of the four common isomers of BHC, water-soluble compounds are produced most readily from the α- and γ-isomers and much less readily from the δ- and β-forms. Two-dimensional chromatography has revealed eleven well-defined compounds from both γ- and α-BHC; these have not been identified, but there is evidence from paper electrophoresis that eight of the eleven compounds from these two stereoisomers are the same. It is unlikely that all the metabolites are trichlorobenzene derivatives, and it is possible that benzene derivatives (by dechlorination) are intermediate stages in the production of some of these metabolites. Comparative tests on a number of insect species have shown that even normal houseflies are exceptionally able to convert γ-BHC to excretable, water-soluble metabolites, and this factor may predispose this insect to the acquisition of insecticide resistance.

It is concluded that the reduced absorption and the increased amount of metabolism are not alone sufficient to explain the increased resistance. These two factors give at the most a sixfold difference in BHC content between normal and resistant flies, while resistance has increased by a factor of one hundred. However, it is possible that a combination of reduced absorption, increased metabolism and redistribution of the poison in the insect might provide the explanation.

The concluding paper in the afternoon was given by F. P. W. Winteringham on biochemical factors in the natural and acquired tolerance of insects to insecticides. It was pointed out that, when an insecticide is applied to an insect, it may be attacked by the tissue enzymes with the formation of metabolites which may be more or less toxic than the insecticide itself. An example where the metabolite is more toxic than the original chemical is parathion, which is a poor inhibitor of cholinesterase. Parathion is known to be oxidized by the insect *in vivo* to the oxygen analogue paraoxon, which is a potent inhibitor of cholinesterase. Similarly, it has been established that 'Schradan' becomes oxidized to a monophosphoramide oxide or a compound very much like it. The process occurring in these two examples might be referred to as toxication. The conversion of insecticides to harmless metabolites or detoxification has been demonstrated with DDT and BHC, particularly with insects resistant to these poisons. It has now also been established that the pyrethroids undergo detoxification in the adult housefly, and there is some evidence that the detoxification process is not one of simple hydrolysis.

The increased detoxification of poisons by resistant insects when compared with normal insects might be either a consequence or a cause of the insects' survival, there being evidence for and against either possibility. Extensive detoxification may occur in normal insect strains, and this must be a factor in their normal tolerance. Detoxification may be inhibited by the presence of certain adjuvants applied simultaneously with the insecticide. A complete understanding of the DDT-resistance problem implies a better understanding of DDT action *in vivo*. Recent work indicates that DDT may, in normal strains of insect, interfere with the oxidative formation of the vital tissue substance adenosine triphosphate. The interference was not observed in a resistant strain, and it may therefore be an additional biochemical factor in DDT-resistance mechanism.

When the evidence provided by all the papers given at the symposium is considered, it appears that results are steadily being accumulated on the changes of resistance that occur naturally and that are produced by the application of an insecticide. However, little progress has, as yet, been made in demonstrating the causes for the differences in resistance that are found, and this work is severely handicapped by lack of knowledge of the mode of action of insecticides.

THE 74-IN. REFLECTOR OF THE COMMONWEALTH OBSERVATORY, MOUNT STROMLO, CANBERRA

EARLY in 1947, the Commonwealth Astronomer, Prof. R. v. d. R. Woolley, supported by the then Astronomer Royal, Sir Harold Spencer Jones, and the board of visitors of the Commonwealth Observatory at Canberra, laid before the Minister for the Interior, the Hon. H. V. Johnson, proposals relating to the establishment of a large reflector at Mount Stromlo.

Among the arguments advanced for the placing of such a telescope at Mount Stromlo was the fact that telescopes of 72-in. aperture or more are to be found almost exclusively in the northern hemisphere. Even at the present time, with the Stromlo instrument operating, the situation is still unbalanced, for there are two such instruments in the south as against nine (including those under construction) in the north.

Cabinet approval was given for the construction of the instrument, and in 1948 an order for a 74-in. telescope complete with building and dome was

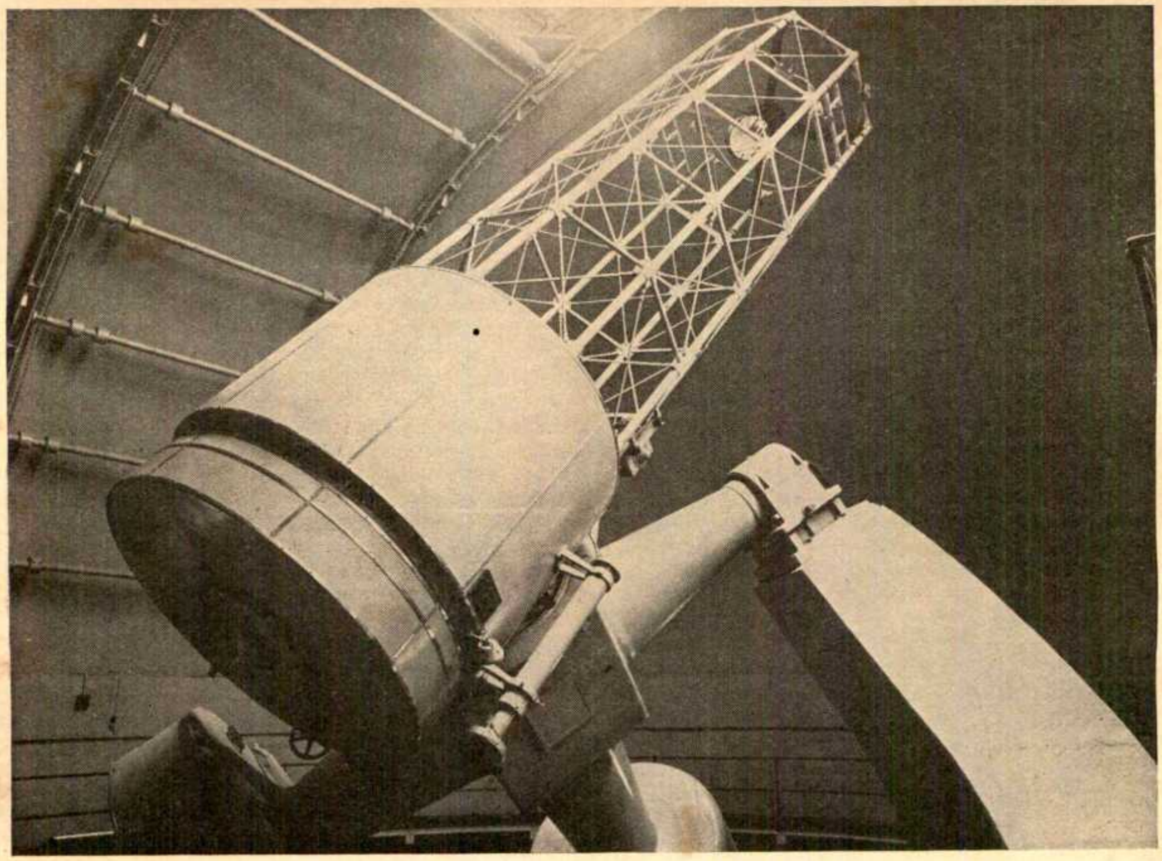

Fig. 1. The 74-in. reflector at Mount Stromlo Observatory. By courtesy of the News and Information Bureau, Department of the Interior, Commonwealth of Australia

placed with the firm of Sir Howard Grubb Parsons, England. The mounting was finished early in 1951 and, after display in the Festival of Britain, was sent to Mount Stromlo. By early 1954 all parts of the telescope and dome were delivered with the exception of the aluminizing plant.

The telescope was formally opened by His Excellency the Governor-General, Sir William Slim, on November 8, 1955. The opening ceremony was held in the dome with the then Minister for the Interior, the Hon. W. S. Kent Hughes, in the chair. Mr. Kent Hughes referred to the labours of the Commonwealth Astronomer in initiating the project and wished him every success in taking up his new post as Astronomer Royal at the Royal Greenwich Observatory, Herstmonceux. Sir William Slim concluded his address by pressing a button, which caused the shutters of the dome to open.

Prof. Woolley then demonstrated the operation of the telescope to an audience of nearly two hundred people, representatives of academic, scientific and departmental activities in Canberra.

The total weight of the moving parts of the new equipment is 40 tons. The main mirror is 74 in. in diameter, 11½ in. thick, and weighs 4,000 lb. The building and dome housing the new telescope provide a controlled ventilation system designed to keep the interior of the dome at as near to night temperature as possible during the day. The dome weighs about 100 tons and can move at a speed of one revolution in five minutes. The rotation of the dome allows any part of the sky to be viewed.

The instrument is designed for use at the Newtonian, Cassegrainian and coudé foci with the respective aperture ratios of $f/5$, $f/8$ and $f/28$. Photographs have also been made at the prime focus for testing purposes, but regular operation in this position is not contemplated. The instrument is arranged on an English-type mounting and access to the Newtonian focus is effected by a platform which moves up and down the opening of the 62-ft. diameter dome.

OBITUARIES

Dr. Sunder Lal Hora

Dr. Sunder Lal Hora, well known to many zoologists in Great Britain, died suddenly on December 8; he was due to retire from his post as director of the Zoological Survey of India this coming June. Hora was born at Hafiazabad in the Punjab in 1896 and educated at the Anglo-Sanskrit High School at Jullundur. Thence he went to Government College, Lahore, where he came under the influence of Prof. John Stevenson and had a distinguished career as a student, obtaining the M.Sc., in part for work on the "Fish of Lahore", and receiving the Maclagan Gold Medal and Purse of the University of Punjab. The same year, 1919, he joined the Zoological Survey of India as a research scholar and less than two years later was appointed to the permanent staff. It was here that he became closely associated with Dr. Nelson

Annandale, of whose help and inspiration he always spoke with affection. In this service he spent the rest of his life, with the exception of 1942–47, when he was director of fisheries for Bengal, returning to the Survey as its director in 1947. He was awarded the D.Sc. of the University of Punjab in 1922 and of Edinburgh in 1928.

Dr. Hora was an indefatigable and careful worker and his many publications cover various fields. He was primarily a systematic ichthyologist and the admitted authority on the freshwater fishes of India and adjacent lands. This statement without qualification could convey a false impression of his breadth of outlook. A number of his systematic papers contain bionomic and ecological observations. The latter aspect induced him to consider the adaptation and the evolution of the adaptive mechanisms of animals to the severe conditions in torrential streams, and his best-known publication in this field (*Trans. Roy. Soc.*, 1930) is mainly devoted to insects.

In trying to comprehend the pattern of the distribution of freshwater fishes in India and Malaya, Dr. Hora was led to consider the past geological history of these areas, and particularly that of the changing river systems brought about by Himalayan tectonic movements, and he put forward an ingenious explanation known as Hora's Satpura hypothesis. From an early stage he became interested in fisheries and means of increasing their efficiency with due regard to conservation. Later, he tackled the pond culture of fish with the view of increasing the food supply. The work and enthusiasm he put into this led to his being invited to open a discussion on the subject at the United Nations Conference at Lake Success in 1949. As fisheries consultant to the Food and Agriculture Organization he recently completed a "Handbook on Tropical Fish Culture".

Dr. Hora's command of Sanskrit enabled him to assess the knowledge of fish and fisheries possessed by the ancient Hindus and so make a significant contribution to the history of Indian science.

Dr. Hora was very active outside his own post and held important positions in various scientific societies and organizations. In recognition of his work he received a number of awards and honours, both in his own country and abroad; but he remained a most approachable and companionable man who willingly placed his knowledge at the disposal of others and, in particular, younger workers, many of whom he encouraged at critical stages in their careers. With his death India has lost a distinguished zoologist and loyal son, and many zoologists in other parts of the world will mourn a friend.

C. H. O'Donoghue

SUNDER LAL HORA's research career was dominated by the materials and concepts he had inherited from Nelson Annandale, and he succeeded in creating new vistas of biological discovery in India. He took Indian ichthyology back to ancient history, prehistory and palæontology, and forwards to a systematized historical understanding continuously related to the material and cultural welfare of the Indian people. His emphasis throughout has been on relationships: from the immediate relationships he described to the larger relations between science, the humanities and politics.

He believed in generalizations based on the growth of intensive specialization into a many-branched unity.

At home he was a kindly patriarch, sometimes looking askance, but tolerantly, at the departures from Punjabi custom of his children; for him the day started with the prayers he had learned in childhood. He was humble, affectionate, considerate, addicted to tabulating routines which never reached the level of work-disciplines, eager for new experiences (he had travelled extensively in most countries), quick to laugh, and quite unable to control his passion for shop talk. On one occasion in London in the autumn of 1953, when he had talked zoology before, through and after dinner, Mrs. Hora whispered to a friend, with a wealth of loving understanding in her voice, "It is always so—nothing but fish!"

He lived a full life, with many sorrows and satisfactions, but remained astonishingly unsophisticated. After his first heart attack, he compromised with decadence by rising at 5.30 a.m. instead of earlier. He could not adjust himself to slowing down, and when I stayed with him in Calcutta a year ago, he made it clear that he would rather die at work than live as a semi-invalid. He died as he wished. He collapsed while presiding over a meeting of the Asiatic Society, but not before calling upon a member to take the chair. It was, characteristically, the last public gesture of a man whose life was distinguished by service and integrity. Cedric Dover

Mr. Frank C. Willcocks

In a few years time Frank Willcocks may become one of those "that have no remembrance", because of his own modesty, and because of his isolation for thirty years in Egypt, yet those of us who had been his colleagues recognized his possession of 'the Darwin touch'.

The influence of Theobald at Wye diverted his intention from farming to entomology, and so to an appointment with the Khedivial Agricultural Society when its eight-room laboratory was founded in 1904, a chemist and a botanist being his colleagues. Within two years he was able to outline the three major pests of cotton in a hundred pages of the Society's Year-book, and this succinct account by a non-graduate student aged twenty-four is still a standard reference.

He remained with the Society until 1930, designing and founding its Cotton Museum as a side-issue, then retired to Bournemouth, whence he moved after the death of his French wife to a bungalow in the woods near Battle. The toil of struggle with his orchard and garden, workshop and housekeeping, lonely except for his friends the cats, led him at last to move to the home of a niece in Gloucester, where he died unexpectedly only a few weeks later on December 18 at the age of seventy-two.

The introduction to his last publication in 1937 (the third volume of "Insect and Related Pests of Egypt") gives a clear impression of his sincerity and quiet wit, his humility towards the specialization of his juniors, and his gratitude for help by lesser men. He was a scientist in grain, the infinite capacity for taking pains being combined with a wide view across the field of his economic problems; he was a pioneer. In that last volume he devotes particular attention to one of his favourite insects, treating the mole-crickets almost affectionately, alternating between the ingenious additions to our knowledge of them which he made and his repeated emphasis on knowledge about them still to be sought. His dealings with the velvety strength of *Gryllotalpa*, burrowing, swimming and flying, showed him to have been a great naturalist.

Willcocks took occasion to investigate patiently some unique opportunities. The invasion of a new scale-insect which destroyed the Lebbek avenues of Cairo was the first of them. Another was the arrival in Egypt of the pink boll-worm, which quickly became the major pest of cotton for many years; arising out of his studies about its queer resting-stage in the seed, he invented the heat-treatment which has for decades been applied as compulsory routine at every ginnery in the country; the credit went elsewhere. His quiet enthusiasm enlisted many willing amateur helpers before professional entomologists became abundant, and his reputation was in no way diminished when the newcomers found that they could accept his fundamental observations.

The Cotton Museum exercised his ingenuity, and his craftsmanship produced some noteworthy exhibits in collaboration with his wife and his artist brother-in-law, A. Morel; there were some witty private fantasies as well. Writing results was a painful necessity, and because his publications were made in Egypt they are little known elsewhere. Unfortunately the three volumes already mentioned weigh more than half a stone apiece, with three-inch page margins, so that their unwieldiness restricts their use.

Willcocks leaves memories of gentle pessimism; of devotion to his friends, whether human, feline or even invertebrate; of industry in spite of recurrent invalidism. It must be a matter for regret that Britain found no means for making use of the latter half of a life from which Egypt had profited so much.

W. LAWRENCE BALLS

NEWS and VIEWS

Photographic Science: Dr. C. E. K. Mees, F.R.S.

BY the retirement of Dr. Kenneth Mees from his position as vice-president in charge of research of the Eastman Kodak Company, industry has lost one of its foremost research directors. While many have the satisfaction of looking back on widely applied technical improvements for which they have been responsible, few can claim to have altered the whole aspect of an industry; Mees is one of them. At University College, Sir William Ramsey dissuaded Mees from an academic career, and in 1906 he joined the firm of Wratten and Wainwright, Ltd., of Croydon, as partner and joint managing director—at a salary of £3 per week! At that time the photographic industry depended largely on empiricism for its advance, and this appointment presented a wonderful opportunity to a trained scientist of exceptional ability. Mees was not slow to take full advantage; he was the first to market panchromatic materials, and by proper application of spectrophotometry was able to produce a comprehensive series of light filters (Wratten filters) which were the first commercially available products in this field. At this time industrial research laboratories were rare; but with characteristic foresight George Eastman decided to establish one at the Eastman Kodak Company's plant at Rochester, N.Y. Mees was invited to organize this development; but he was reluctant to leave his firm, so Eastman purchased Wratten and Wainwright, Ltd., and in 1912 Mees went to the United States to commence his duties. Since that date the work of the laboratory has covered both fundamental and applied research, and has not been confined to subjects of immediate connexion with photography.

In a special division of the laboratories which Mees established for research on photographic emulsions, much of the early development work leading to the great advances in photographic materials has been carried out. Of special importance for science was the working out of a wide range of plates and films for spectrographers and astronomers. Among the other notable contributions to photography made by Kodak during the period when Mees was director of the Research Laboratories were the introduction of panchromatic materials, of 16-mm. (and later 8-mm.) Cine Kodak film and equipment in 1923, and 'Kodachrome' film in 1935. Other activities include the establishment in 1918 of a department for the manufacture of synthetic organic compounds to replace German supplies, which has now become the Eastman Organic Chemicals, and work on molecular distillation, which was applied successfully to the extraction of vitamins from cod liver oil and has resulted in Distillation Products, Inc. Mees's books on photography culminated in his "Theory of the Photographic Process", published in 1942 and completely revised in 1954. His wide interests are reflected in "The Organization of Industrial Scientific Research", written in collaboration with J. A. Leermakers; but his breadth of vision is best illustrated by his philosophical discussion of the history of science in relation to world history—"The Path of Science". He was elected an Honorary Fellow of the Royal Photographic Society in 1921, and received the Progress Medal of this Society in 1913 and again in 1953. In 1939 he was elected a Fellow of the Royal Society, and in 1950, after he became an American citizen, a member of the U.S. National Academy of Sciences.

Dr. C. J. Staud

DR. CYRIL J. STAUD now succeeds Dr. Mees as vice-president in charge of research and development, Eastman Kodak. Staud graduated at the University of Rochester, N.Y., and obtained a Ph.D. degree at the Massachusetts Institute of Technology. He joined the Kodak Research Laboratories in 1924, where his ability gained for him positions of increasing responsibility. In 1931 he was appointed superintendent of emulsion research, and was appointed director of the Research Laboratories in 1947. His energies have been devoted to the internal organization of the laboratories, so that he is not as well known outside the firm as his achievements would warrant. He has an astonishing grasp of the details of the wide activities of the Laboratories, and is outstanding in organizing and inspiring effective and enthusiastic team-work. His managerial skill is supplemented by a keenly inventive mind, and he has been responsible for many of the Company's scientific achievements. Although Dr. Mees's retirement is a sad loss to the organization, and to industry generally, the research activities of Eastman Kodak have been left in capable hands.

Progress Medal of the Royal Photographic Society : Dr. J. D. Kendall

The Silver Progress Medal of the Royal Photographic Society has been awarded to Dr. J. D. Kendall, head of the Renwick Laboratory of Ilford, Ltd., in recognition of his distinguished contributions to research in the chemistry of photographic processes and materials. Dr. Kendall is known for his work in relation to photographic emulsion sensitizers, emulsion stabilizers, colour couplers, developing agents and desensitizers. His discovery, some twenty years ago, of particular *p*-dialkylaminobenzylidene derivatives of compounds having a reactive methylene group activated by carbonyl (the merocyanines) as efficient optical sensitizers for emulsions, was a starting-point for advances of considerable consequence in emulsion technology. In 1935 he proposed an original theoretical principle for relating the chemical structure of sensitizers, desensitizers and developing agents to their respective properties, and his name is now linked with those of Andresen and Lumière in the 'Andresen–Lumière–Kendall rules' for photographic developing agents. Dr. Kendall's relatively recent discovery of 1-phenyl-3-pyrazolidone (phenidone) as a developing agent has led to greatly improved commercial developers and has also initiated a great deal of research on superadditivity phenomena in photographic laboratories throughout the world. Even more recently (1954) he has described, in collaboration with G. F. Duffin, a new class of optical sensitizers, namely, the immazolenine cyanines. The Progress Medal was instituted in 1878, and this is the forty-fourth such award, twenty-two being to persons of foreign nationality ; it is awarded for any invention, research, publication or exhibition which leads to an important advance in photography.

British Broadcasting Corporation : Miss Mary Somerville, O.B.E.

With the retirement in January of Miss Mary Somerville from the B.B.C., one of the links with the pioneering days of 2*LO* has been broken. Miss Somerville joined the B.B.C. in 1925 as assistant to the then educational director, J. C. Stobart, having been attracted to the new field of intellectual adventure through the broadcasts of Sir Walford Davies. Within four years she had taken full charge of the embryonic Schools Department, and imbued by a strong sense of educational purpose, in the eighteen years of her active direction of this Department she carved out a unique place for this activity of the B.B.C. in the educational history of our time ; and this in the face of considerable resistance from the vested interests of the essentially conservative educational world. In 1947 she toured the Commonwealth and on her return became assistant controller of Talks Division, thus entering a field where she could to an even greater extent explore the radio medium as a means of communication. Three years later she took over one of the toughest assignments in the whole B.B.C. organization, that of full controller of Talks Division, and as such became the Corporation's first and only woman controller. With the whole of the Corporation's Talks output under her control, the world of science was not the least of her interests, and the present position of the B.B.C.'s science talks owes not a little to her sympathetic understanding of the problems that face the producer who is presenting science to a mass audience.

Mr. John Green

The new controller of talks, Mr. John Green, also had connexions with science, if in the applied field, namely, agriculture. Mr. Green comes from a Gloucestershire landowning family. He went up to Cambridge, where he was President of the Union, and was afterwards called to the Bar. In 1934, however, he joined the B.B.C. and specialized in the production of agricultural talks, being the Corporation's agricultural liaison officer until he became Miss Somerville's chief assistant a number of years ago. Thus the new controller has risen from the ranks, as it were ; he is familiar with the professional problems concerned with talks production and sees in the producer a public servant with a valuable part to play in bridging the gap between those who have something to say and those who are prepared to listen.

British Iron and Steel Research Association : Dr. J. Pearson

The British Iron and Steel Research Association has appointed Dr. J. Pearson as assistant director of research, to assume such duties as are delegated to him by the director, Sir Charles Goodeve ; Dr. Pearson will continue his present duties as head of the Steelmaking Division and Chemistry Department of the Association. After graduating from the University of London in 1933, Dr. Pearson did some research in organic chemistry, and then joined the Research Department of Tube Investments, Ltd., to carry out work in connexion with the manufacture of steel tubes and allied products. During 1937–46 he was employed in the explosives branch of the Armament Research Department, Ministry of Supply, and obtained his Ph.D. in 1946 for research work on the polarography of organic compounds. After the Second World War he joined the British Iron and Steel Research Association as head of the Chemistry Section of the Swansea laboratories, where he was largely concerned with problems on the disposal of spent pickle liquor. He was appointed head of the Chemistry Department in 1950, assuming the additional duty of head of the Steelmaking Division four years later.

Nuffield Foundation Awards in Dentistry, Biology and the Social Sciences

The Nuffield Foundation is offering a number of fellowships, scholarships and bursaries in the fields of dentistry, biology and the social sciences. The fellowships for dentistry are for persons, aged 25–35 years, with dental qualifications to receive additional training in pure and applied science so as to fit them for an academic career in dentistry, and also to enable graduates in medicine and science to receive training (not necessarily for a registrable dental qualification) so as to undertake teaching and fundamental research on dental health and disease. (It is to be noted that in past years few applications have been made by those eligible in the latter category.) The fellowships are worth £500–800 a year for one to three years, and applications must be received by March 1. The dental scholarships, normally for one year only, are for students at university dental schools in the United Kingdom and cover tuition fees and a subsistence allowance of not more than £200 ; applications must be received by June 30. The Foundation's scholarships and bursaries in biology and the social sciences are for graduates of British universities, preferably within the age-group 22–35 years. The awards in biology are for graduates in physics, chemistry, mathematics or engineering to receive such training in biology as will enable them to undertake research and teaching in the biological sciences in the United Kingdom. The scholarships, which are for those with postgraduate (non-biological) research experience, are worth £500–600 a year, and the bursaries £350 a year; in each case, fees, a marriage allowance of £50 a year and a family allowance of £50 per child will be paid. Applications must be received by April 1. The awards for social sciences are similar to those for biology, except that applications must be received by May 1, and the holder may have a degree in any academic subject other than the social sciences, psychology or the social sciences; subjects suitable for study by holders are political science, social psychology, anthropology, social statistics and sociology generally (but not economics). Applications for all these awards, and further information, can be obtained from the Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

Industry and Nuclear Power in Britain

QUESTIONED in the House of Commons on February 15 as to the Government's policy regarding the utilization by private firms of technical information on the industrial applications of nuclear power, the Lord Privy Seal, Mr. R. A. Butler, stated that it is the policy of the Atomic Energy Authority to encourage access by private firms to such information in order that industry may participate more fully in these important new developments. Steps are being taken to ensure that firms are not enabled to obtain exclusive rights on the basis of information supplied by the Atomic Energy Authority. In reply to further questions, Mr. Butler said he would discuss with the Minister of Fuel and Power, Mr. Aubrey Jones, the question of letting the House have the maximum information which it is in the public interest to disclose on this new phase in the relationship between the State and private industry on Mr. Aubrey Jones's early return to Britain.

Electronic Computers in Molecular Quantum Mechanics

THE importance attached to the use of modern electronic computers in molecular quantum mechanics has been stressed in an International Conference held in Texas during December last. A resolution was passed unanimously, directing attention to the impressive results already obtained by high-speed computers in the calculation of molecular and crystal properties, and claiming that these properties are of extreme importance in chemistry, physics and biology. The resolution goes on to note that "progress of this work is greatly hampered by the fact that, due to their great cost, high-speed computers are unavailable to most scientists in this field"; and therefore it "recommends that governments, industries, foundations and private philanthropists give special attention to the problem of providing more high-speed computing facilities for use in molecular problems". Copies of the complete document are being sent to government and other scientific agencies in Britain, the United States and elsewhere.

This matter is highly important so far as Britain is concerned. It is believed that the University Grants Committee contemplates the provision of a limited number of these computers during the next quinquennium. But it would be a great pity if the number is unrealistically small. For, as Prof. D. R. Hartree and others have pointed out, electronic computers have entirely changed the kind of problem (such as the structure of vitamin B_{12} or a single protein molecule) which can be attacked successfully. As things are now, certain calculations have to be sent from Britain to the United States, since they cannot be dealt with adequately in British universities. One American firm alone expects to have nearly two thousand large computers in use at the end of another eighteen months or so. It is imperative that universities in Britain—and other institutions—should have calculating facilities which such machines alone can provide.

Artificial Rain-making in India

A SYMPOSIUM on artificial rain was held in India in February 1953 under the joint auspices of the Atmospheric Research Committee, Council of Scientific and Industrial Research, and the India Meteorological Department, the purpose of the symposium being to review the present status of rain-making operations, to discuss recent progress and to make recommendations for extending research in India on cloud physics. The proceedings have now been published (pp. 148. New Delhi: C.S.I.R., 1955). Of the twelve papers, six are concerned with the formation and physical characteristics of clouds in different parts of India. It appears that the release of showers by the coalescence of water drops in non-freezing clouds is a common occurrence, and there was some discussion on the possibilities of artificially stimulating this mechanism by spraying the clouds with water droplets. It was concluded that, in India, the possibilities of producing economically significant quantities of rain by artificial seeding techniques are rather limited, largely because of the low frequency of cloudy days without rain in dry areas. In a long paper, Banerji and Mukherji describe their laboratory studies on nucleation and condensation, and also some cloud-seeding experiments which they have carried out near Calcutta. Hydrogen-filled balloons were used for releasing either dry ice, a spray of cold water or a charge of gunpowder impregnated with silver iodide at a predetermined altitude. Unfortunately, the physical reasoning used by these authors is not always sound, and their field experiments, although showing commendable enterprise, were not well conceived. Their observational techniques were also inadequate for a proper assessment of the results. A number of workers gave sober appraisals of the present status of rain-making trials in other countries and very properly stressed the need for more fundamental research in cloud physics and the training of more scientists in this field. The principal outcome of the meeting was a recommendation to the effect that a cloud physics research unit be set up to undertake fundamental research, and a rain research unit be established having aircraft and radar facilities for planning and conducting field experiments. These proposals show not only enthusiasm but also an appreciation of the importance and magnitude of the problem. India has set an example which other countries, with far greater scientific resources, might do well to follow.

Medical Research and its Benefit to Humanity

IN his Stephen Paget Memorial Lecture, "Humanity's Rising Debt to Medical Research", given before the Research Defence Society on November 16, Sir Henry Dale referred to the convincing evidence of the success of inoculation against diphtheria, which has become available since he lectured to the Society in 1931. Systematic inoculation began in Hamilton, Ontario, in 1925, and the death-rate from diphtheria fell so steeply that after 1930 there were no more deaths and after 1933 no more cases. In Great Britain a full-scale preventive inoculation campaign was not inaugurated by the Ministry of Health until 1940 and was not fully under way until 1942. In 1940 there were still in England more than 45,000 cases of diphtheria, and more than 2,400 of these were fatal. As inoculation became effective, in spite of a counter-campaign, the numbers fell steeply and steadily until in 1954 there were only 173 cases; of the nine deaths, six were in children less than fifteen years old, and all in the minority who had not been inoculated. The value of preventive inoculation against tetanus is a more recent discovery, but there were only seven cases among the sixteen thousand wounded in the British Expeditionary Force in fighting its rearguard action to Dunkirk over soil known to be highly dangerous as a source of tetanus infection; these seven cases were all in the 10 per cent minority who had been persuaded to refuse protective inoculation.

Sir Henry also pointed out that the discovery of successful methods for immunizing dogs against distemper and the crippling condition known as 'hard pad' had, too, met a persistent campaign to induce owners to refuse this protection for their dogs. Sir Henry outlined some of the outstanding medical discoveries which had resulted from the experimental method during the past twenty-four years, such as mepacrine, the sulphonamides and penicillin, and the new types of anæsthetics; the use of some of these, such as curare, is still exposed to a cruel, if ineffective, campaign of denunciation and misrepresentation. The Research Defence Society, he said, needs and deserves all the support it can get in combating this attitude of blind obstruction.

Linen Research Association: Report for 1955

The report of the Council of the Linen Research Association for the year ended September 30, 1955 (pp. 20; from the Association, Lambeg, Belfast; 1955), refers to the support forthcoming from all sections of the industry—this in spite of the difficulties of the industry, which has not recovered from the setback of 1952. A special committee has been appointed to put before the Industrial Grants Committee of the Department of Scientific and Industrial Research a statement of the Association's policy and programme for the next five years and of its financial needs, and the Department has agreed to continue the present terms of grant for the first year of the new quinquennium, while raising the contribution needed to earn the maximum grant from £32,000 to £40,000 for the last four years of the quinquennium and the maximum grant itself from £22,000 to £25,000. The Association has experienced increasing difficulty in recruiting new staff, and in its spinning research has given priority to a new servo-drafting control mechanism, which should improve the regularity of dry spun yarns and the dry spinning of flax to finer counts, and to a modified ring system for wet-spinning. A pneumatic tension gauge has been developed for measuring tensions on winding machines and dry-spinning frames, and means have been devised for restricting the size of the yarn balloon when warping linen yarns at high speed. Attention has been given to improved methods of applying vat dyes to linen fabrics and to the application of resins and other polymers to linen fabrics.

In connexion with the difficulties of the linen industry, it may be noted that, replying in an adjournment debate in the House of Commons on January 31, the Parliamentary Secretary to the Board of Trade justified the Government's decision to close the flax processing mills operating in Great Britain. He said that, unless considerable sums are spent on plant and new machinery, many years of operation and research will be required to do more than touch the fringe of the problem, and the Government does not consider that continued expenditure of £500,000 a year from public funds to maintain a small scheme covering 16,000 acres of land is justified.

Capper Pass Awards for Papers on Metallurgy

The following Capper Pass Awards have been made by a joint committee representing the Institution of Mining and Metallurgy and the Institute of Metals for papers published during 1955 in the *Transactions* of the Institution and the *Journal* of the Institute: £100 to Dr. Maurice Cook, C. L. M. Cowley and E. R. Broadfield (use of refractories in low-frequency induction furnaces for melting copper alloys); £100 to P. M. J. Gray (extraction of uranium from a pyritic ore by acid pressure leaching); £50 to W. T. Edmunds and R. C. Lloyd (production of light-alloy drop forgings, their heat treatment, inspection and testing). The Awards are made from a fund given by Capper Pass and Son, Ltd., for the encouragement of scientific and technical papers dealing with processes and plant used in extraction metallurgy and on the subject of assaying, and also papers and processes used in all branches of the non-ferrous metal industry.

City and Guilds of London Institute: Fellowships

The fellowship of the City and Guilds of London Institute has been conferred upon the following past students of the City and Guilds College or of Finsbury Technical College in recognition of their distinguished contributions to industry and the engineering profession: Dr. R. T. Colgate, chief technical works manager and chief chemist, Huntley and Palmers, Ltd., Reading; E. W. Moss, senior partner of Raworth, Moss and Cook, chartered patent agents; J. F. Pain, director of Dorman Long (Bridge and Engineering), Ltd.; B. G. Robbins, secretary of the Institution of Mechanical Engineers; and Dr. F. H. Rolt, formerly superintendent of the Metrology Division of the National Physical Laboratory, Teddington.

Psycho-Analysis and Contemporary Thought

The British Psycho-Analytical Society is arranging a series of six evening lectures commemorating the centenary of the birth of Sigmund Freud; they will be given in the Friends House, Euston Road, London, N.W.1, under the general title of "Psycho-Analysis and Contemporary Thought". The dates, lecturers and subjects are as follows: April 13, Marion Milner (psycho-analysis and art); April 17, Donald W. Winnicott (psycho-analysis and the sense of guilt); April 24, Dr. Roger Money-Kyrle (psycho-analysis and philosophy); April 27, Dr. Elliott Jaques (psycho-analysis and social problems in industry); May 1, Dr. John Bowlby (psycho-analysis and child care); May 8, Dr. Ilse Hellman (psycho-analysis and the teacher). Tickets (4*s.* each lecture or 1 guinea the series) and further information can be obtained from the Administrative Secretary, British Psycho-Analytical Society, 63 New Cavendish Street, London, W.1.

Advanced Courses in Technology

A MOST useful booklet for all in the London area who are interested in advanced technological studies has been prepared by the London and Home Counties Regional Advisory Council for Higher Technological Education. The booklet describes all the courses which are available and which are not announced in college calendars or prospectuses. They are, as a rule, part-time (usually evening) courses; but full-time courses which are specially arranged and are not of longer than three months duration are also included. The courses range from silicone polymer technology to the organization of civil engineering contracts and from advanced archive administration to the industrial applications of servo-mechanisms. The booklet is clearly indexed and gives particulars of the venues of courses, the lecturers, and the approximate fees. Copies can be obtained from the Secretary, Tavistock House South, Tavistock Square, London, W.C.1.

The Night Sky in March

NEW moon occurs on March 12d. 13h. 36m., U.T., and full moon on March 26d. 13h. 11m. The following conjunctions with the Moon take place: March 3d. 15h., Saturn 3° N.; March 11d. 0h., Mercury 7° S.; March 16d. 04h., Venus 1° S.; March 23d. 15h., Jupiter 6° N.; March 30d. 23h., Saturn 3° N. Mercury is too close to the Sun during the month for observation. Venus sets at 21h. 30m., 22h. 15m. and 23h. on March 1, 15 and 31, respectively, its stellar magnitude varying between −3·6 and −3·9 and the visible portion of its illuminated disk decreasing from 0·701 to 0·575; during the month its distance from the Earth decreases from 96 to 75 million miles. Mars rises at 3h. 50m., 3h. 25m. and 3h. on March 1, 15 and 31, respectively, and lies rather low in the constellation Sagittarius, in which it has an eastward movement and is a little south of α Sagittarii on March 23; its stellar magnitude varies between 1·2 and 0·8, and its distance from the Earth between 146 and 122 million miles during the month. Jupiter is visible throughout the night, setting at 6h. 25m., 5h. 30m. and 4h. 25m. at the beginning, middle and end of the month, respectively, and has a westward movement in Leo; its stellar magnitude varies between −2·0 and −1·9, the small decrease in brightness being due to its distance from the Earth increasing from 410 to 435 million miles. Saturn rises at 1h. 10m., 0h. 10m. and 23h. 10m. on March 1, 15 and 31, respectively, and lies rather low for good observation in Scorpius, a little north of β Scorpii; its brightness increases by 0·2 mag. owing to its distance from the Earth decreasing from 909 to 867 million miles during the month. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: March 18d. 19h. 36·1m., ι Tau. (*D*); March 22d. 23h. 45·9m., κ Cnc. (*D*), *D* referring to disappearance. The Sun enters the first point of Aries on March 20d. 15h. 21m.

Announcements

SIR EDWARD APPLETON, principal and vice-chancellor of the University of Edinburgh, will deliver the Reith Lectures for 1956. The lectures, "Science and the Nation", will be broadcast on the B.B.C. Home Service in the autumn.

THE Countess of Albemarle and the Right Hon. Lord Justice Morris have been appointed additional members of the University Grants Committee on matters relating to academic salaries only.

PROF. J. PIVETEAU, professor of palæontology in the University of Paris, has been elected a member of the Geology Section of the Paris Academy of Sciences in succession to the late Prof. A. Michel-Lévy.

THE Ninth International Botanical Congress will be held in Montreal during the summer of 1959. Preparations for the Congress have been initiated, but the exact date and officers of the Congress will be announced later. For the present all communications should be addressed to the Secretary of the Executive, Dr. A. J. Skolko, Botany and Plant Pathology Division, Science Service Building, Carling Avenue, Ottawa, Ontario.

A MEETING of the Malacological Society of London will be held on March 14 at 6 p.m. in the rooms of the Linnean Society, Burlington House, London, W.1, when "Pelagic Mollusca: Swimmers and Drifters" will be considered. Four papers will be read, and then the meeting will be thrown open for discussion. Further information can be obtained from the honorary secretary of the Society, G. I. Crawford, 18 East Drive, Carshalton, Surrey.

A SHORT course on the elements of radiological protection (that is, personal safeguards against radiation) will be held at the Isotope School, Atomic Energy Research Establishment, Harwell, during April 9–13. The course will consist of lectures and practical work and is primarily intended for industrial users of radioactive isotopes. Application forms and further details can be obtained from the Isotope School and, as the number of places is limited, these should be returned before March 9.

THE Industrial Committee of the Scientific Film Association is organizing a course on "First Steps in Industrial Film Making", to be held during March 5–8 at "Wansfell", Theydon Bois, Essex, a residential college of the Essex Local Education Authority. The course is not for those engaged professionally in the making of films but rather for those in industry who may have occasion to make a film (16 mm. silent or sound) in such fields as work study, the recording of processes or installations, or the simplest forms of illustration for instructional purposes. The course is residential, and the fee is 8 guineas. Further information can be obtained from the General Secretary, Scientific Film Association, 164 Shaftesbury Avenue, London, W.C.2.

THE Ministry of Agriculture, Fisheries and Food is offering the following scholarships for rural workers or the children of rural workers, of seventeen years of age or more: twenty senior scholarships, tenable at universities or colleges, for a degree or diploma in an agricultural subject or veterinary science; thirty junior scholarships and six extensions for existing holders, tenable at farm institutes, for one-year courses. Selection is by interview only. Further information and application forms (to be completed by February 29) can be obtained from the Secretary, Ministry of Agriculture, Fisheries and Food (Room 290), Great Westminster House, Horseferry Road, London, S.W.1, or from education offices of County Councils.

COLONIAL RESEARCH IN THE BRITISH COMMONWEALTH

THE reports for 1954–55 of the Colonial Research Council and of the eight specialist advisory bodies and the Director of the Anti-Locust Research Centre are contained in a substantial publication of more than three hundred pages entitled "Colonial Research 1954–55"[*]. In addition, there are some notes on research matters not covered by the reports of the specialist advisory bodies, and appended is a list of schemes approved for research grants under the Colonial Development and Welfare Acts, April 1, 1954–March 31, 1955. At the end of each of the reports are lists of publications; and, with the membership of the various Councils or Committees and their terms of reference, the publication as a whole gives an impressive picture not merely of the magnitude and range of the effort devoted to research in Colonial problems by Great Britain but equally of the extent to which that effort is interlocked with the research organization generally in Britain whether in the universities or in government establishments. No document better calculated to refute the idea that there is any inherent reproach in the word 'Colonial' could easily be conceived.

The report of the Colonial Research Council points out that with the coming into force of the Colonial Development and Welfare Act, 1955, the provision for 1955–60 calls for an average annual research expenditure of £1,600,000 as against £1,173,381 during the year ended March 31, 1955, and an average of £1,240,000 over the past four years. Expenditure in the several fields of research is at different stages of development, necessitating continuous review of the financial situation, and the Colonial Research Council held the first of such reviews in April 1955 to consider the allocation of the available funds among the various fields of research. The fifty-two new schemes and forty-eight supplementary schemes made during the year, involving grants totalling £533,548, brought the net commitment chargeable against Colonial Development and Welfare Funds since 1940 to £12·5 million. Of the gross allocation of £13·5 million, 32·5 per cent has been for agricultural, animal health and forestry schemes, 15 per cent for medical research, 11·8 per cent for fisheries research, 9·7 per cent for tsetse and trypanosomiasis research, 9 per cent for social science and economic research, 7·9 per cent for insecticides research, 5 per cent for research sponsored by the Colonial Products Research Council, 3·6 per cent for anti-locust research and 5·5 per cent for miscellaneous schemes, including building and road research. About 39 per cent has been for schemes to benefit the East African Territories, 18 per cent for the West African group, 10 per cent for the South-East Asian Territories and Hong Kong, 8·8 per cent for the West Indian Colonies, British Guiana and British Honduras and 5·6 per cent for the Central African Territories.

Much the largest scheme approved during the year was £104,024 for the establishment and maintenance for an initial two years of the East African Scientific and Industrial Research Organization, but £50,000 was provided for the establishment and maintenance of the Colonial Road Research Section at the Road Research Laboratory, Harmondsworth, a supplementary £42,500 for the East African Medical Survey, and a supplementary £37,750 for the maintenance of the Anti-Locust Research Centre and its extra-mural activities. £31,483 was provided for the purchase of buildings at Kabete for the East African Veterinary Research Organization, £22,329 for the establishment of the Agricultural Research Station at Aden, £17,780 for silvicultural research in Nyasaland, and supplementary £16,683 for the Desert Locust Survey, £16,365 for maintenance of the Ebini Livestock Experimental Station, British Guiana, and £14,390 for maintenance of the Colonial Insecticides Research Unit, Porton.

The second annual report of the Colonial Products Council and Colonial Products Laboratory records that the Laboratory dealt with 829 inquiries during the year, and completed eighty-four investigations. Those of major interest included an examination of oil of *Leptospermum citratum*, which indicated a citral content of 40 per cent, and one of the limonene obtained as a by-product in the concentration of sweet orange oil, which showed the limonene to be of good commercial quality. Examination of the oleo-resin collected in an experimental tapping trial from *Pinus caribaea* Morelet in British Honduras was completed and also a second trial distillation on a larger scale. The effects of insect attack on groundnuts were further studied, and five species of illipe nuts that were examined for the agricultural authorities of Sarawak contained 64–66 per cent saturated acids, 33–35 per cent oleic acid and about 1 per cent of linoleic and more unsaturated acids.

Detailed studies were made of the composition of Barbados sugar-cane wax; and a further sample of sisal wax from Kenya gave wax polishes comparable with those obtained by using carnauba wax, but emulsion polishes hardened on standing. A study of the development of acidity in maize under insect attack has been started, and, in further work on the chromatographic resolution of the active principles of pyrethrum flowers, reversed-phase chromatography using silicone-impregnated kieselguhr columns gave a good separation of the pyrethrin I and pyrethrin II fractions. Further progress has been made in building up the reference collection of photo-micrographs of fibres from botanically authenticated plants, and a satisfactory fibre was obtained from experimental yarn produced in a bulk spinning trial on a sample of Nigerian anaphe silk, probably derived from *Epanaphe moloneyi*.

At the Colonial Microbiological Research Institute, Trinidad, a start has been made in following the microbiology of 'microfermatories', and the distribution of free sugars and glycosides in the cacao bean has been studied. Further work on the development of the antifungal antibiotic, comirin, now lies mostly outside the scope of the Institute, but the nature of the antibiotic effect against fungi and yeast has been more closely investigated in an attempt to elucidate the point of attack of comirin on the fungus. The preliminary difficulties encountered at the newly established jute estate near New Amsterdam in British Guiana now seem to have been overcome, and retting dry ribbon no longer seems to be a problem, but the original difficulties point to the necessity for 'seasoning' tanks and using a 'starter'. The Sugar Technological Laboratory, Trinidad, has completed work in connexion with the modernization of the experimental sugar factory, and studies on the variation of cane-juice constituents with plant growth conditions have shown that in the greenhouse a refractory juice can be produced to order by simply controlling the water supply to the cane. Use of sodium fluoride in clarification has been examined critically, and a study undertaken of the thermal conductivity of sugar cane, while a detailed study is being made of the soft fatty fraction obtained as a by-product of wax manufacture.

---

(Reports of the Colonial Research Council; Colonial Products Council; Colonial Social Science Research Council; Colonial Medical Research Committee; Committee for Colonial Agricultural, Animal Health and Forestry Research; Colonial Insecticides Committee; Colonial Economic Research Committee; Tsetse Fly and Trypanosomiasis Research Committee; Colonial Fisheries Advisory Committee; Director, Anti-Locust Research, and Research Matters not covered by the above Reports of the Specialist Advisory Bodies.) Pp. 316. (Cmd. 9626.) (London: H.M.S.O., 1955.) 9s. net.

Investigations into the production of fibreboard from secondary Colonial timbers continued at the Forest Products Research Laboratory, Princes Risborough, where experimental work on the processing conditions for hardboard from four Malayan timbers has been completed. At the University of Birmingham work continued on the synthesis of cellulose by the organisms *Acetobacter acetigenum* and *Acetobacter xylinium*, and on the characteristics of dextransucrase from *Leuconostoc arabinosaceus*, and the mechanism of the reaction between sugars and amino-acids was being investigated using model sugar–amino-acid systems; the anti-acetylcholine activity of several series of compounds, including antihistamine agents, has been determined, and it was observed that introduction of several halogen atoms in the molecules of three classes of antihistamines modified their anti-acetylcholine activity. At the Royal Technical College, Glasgow, the constitution of the triterpene alcohol, taraxerol, has been determined, and investigations into the nature and properties of the undesirable highly coloured constituents of mangrove tanning extracts continued at the University of Leeds. At the University of Nottingham the Colonial hardwood, rengas, has been shown to contain two pigments, the more abundant being probably 4 : 3′:4′-trihydroxybenzylidene-6-methoxycoumarone, with very small amounts of an isomer, and the quantitative aspect of the production of oligosaccharides from glucose and the purification of Floridean starch have been studied at the University College of North Wales, Bangor.

The eleventh annual report of the Colonial Social Science Research Council, to which are appended reports from the East African Institute of Social Research, the West African Institute of Social and Economic Research, the Institute of Social and Economic Research, University College of the West Indies, the Rhodes–Livingstone Institute, the Educational Research Institute for Fiji and Western Pacific Territories, and the Social Research Unit, University of Malaya, expresses the opinion that, while funds available for research by individual scholars will be severely limited, the new allocation of £525,000 should suffice for a reasonable level of activity by the regional Institutes of Social and Economic Research, provided they can attract funds from other sources. Much time was devoted by the Council during the year to the question of making regional institutes ready for transfer as university institutes to the parent universities and university colleges at the end of their present Colonial Development and Welfare period, but the success of these plans depends largely on matters outside the Council's control. The Council for Technical Co-operation in Africa South of the Sahara has set up an Inter-African Committee for Social Sciences, and the first inter-African conference under the auspices of the Committee was arranged at Bukavu during August-September 1955.

The research section of the Department of Social Welfare in Singapore completed a socio-economic survey of family living conditions in Singapore City and also a survey of listening habits and tastes of Chinese households, while in Malaya the Department of Aborigines undertook some ethnological research, mainly to establish the geographical distribution and to collate material on the political and social organization of aboriginal tribes. Twenty-six volumes of the Ethnographic Survey of Africa had been published by the end of the year, and two further volumes were in the press. The first volume of the North Bantu Borderland Linguistic Survey was also ready for the press. A bibliographical survey of available material on labour productivity in British African Colonies is being made, and the preparation of a Ga-Adangme dictionary was started. A study of Iban agriculture, the last of the anthropological studies in Sarawak, is in the press. At the East African Institute of Social Research, work in Buganda was mainly in connexion with the study of change in patterns of authority and social stratification in Buganda and the North Nyanza district of Kenya. The West African Institute of Social and Economic Research expects in the near future, over and above the research programme for its permanent staff, to assist a five-year programme for a cultural history of Benin and a survey of the groundnut- and cotton-producing areas of Northern Nigeria. Research in progress at the Rhodes–Livingstone Institute covers both urban and rural studies, including a social survey of Livingstone, a study of family economics and nutrition in the copper belt of Northern Rhodesia and field work among the Lungu. Studies by the three Fellows comprising the Social Research Unit, University of Malaya, have included an analysis of land usages and transfers at Parit Sulong, with particular reference to the alleged encroachment of Chinese, and an examination of inter-racial attitudes, their bases and rationale, the relation of Chinese farmers at Sungei Derhaka, in Province Wellesley, to the Malays on whose land they have settled and among whom they work, and the social conditions of the inhabitants of a street in the 'Chinatown' area of Singapore.

Six small schemes, applicable to the tropics, two of which were for home-based work at the Universities of Liverpool and London, were added to the twenty-one established research schemes under the supervision of the Colonial Medical Research Committee at the beginning of the year. The Committee's tenth annual report records five new appointments to overseas research units, two of which were to newly created posts, and states that the Colonial medical research studentships are increasingly filling their purpose. Tribute is also paid to the value of the work of the Sub-Committee on the Sickle-Cell Trait in fostering research in this field, while the Helminthiasis Sub-Committee has recommended that a group of young zoologists should be given basic training under recognized specialists in the varied aspects of malacology, in particular the systematics of the snail, at appropriate laboratories at Glasgow, Liverpool, Reading, London and perhaps in Europe or the United States, and also afforded opportunities to study the infestation overseas. The East African Standing Advisory Committee for Medical Research stresses the need for statistical and demographic studies and for co-operation among agricultural, veterinary and medical workers concerned with nutrition. The East African Council for Medical Research held its first meeting in January 1955, and the West African Council for Medical Research met for the first time in March 1955 at Lagos.

Studies on loiasis in the Cameroons and Nigeria have included the continued study of the population of flies and its infection-rate at Kumba and Sapele; the biting-cycle of *C. silacea* at all levels of the forest up to and above the canopy, using an improved technique for scaling the giant trees in the tropical rain forest, and trial of the use of 'Hetrazan' in controlling the transmission of loiasis. It seems likely that use of 'Banocide' for this purpose may be of practical value in developed areas where the population can be adequately covered and monkeys are not a potential reservoir. Infection of captive monkeys (*Mandrillus leucophaeus*) has now been achieved. In East Africa the Filariasis Research Unit has now been merged with the Medical Survey. In Malaya, blood surveys made by the Filariasis Research Unit at Kuantan, along the Pahang River, revealed a high incidence (60 per cent microfilaria-rate in those aged 4–5 years) in young children, and the results suggest that a very high rate of transmission occurs indoors and that most infections are thus acquired. Experiments to find a practicable treatment by 'Hetrazan' continued on carriers of *W. malayi*, and trappings of mosquitoes with Mangoon (stable) traps confirmed that *Mansoniodes longipalpis* (*longipalpis* plus *bonneae*) is the major vector and that it will feed on many animals and is equally attracted to man or goat.

Investigations on guinea-worm at University College, Ibadan, indicate that *Thermocyclops nigerianus* Kiefer is the most widespread intermediate host in south-west Nigeria and is highly adapted to pond water. Laboratory and field studies on the transmission of vesical schistosomiasis continued in the Gambia and, with its further expansion during the year by a group of World Health Organization workers, the designation of the East African Malaria Unit has been changed to the East African Institute of Malaria and Vector-Borne Diseases, to accord with its increasing scope. Continued examination of 'Dieldrin' as a mosquito larvicide has shown it to be some ten times as lethal as DDT, and the granulated form is a valuable new preparation. The Malaria Control Pilot Project in Western Sokoto, Northern Nigeria, found a surprisingly rapid loss of potency of residual 'Dieldrin', DDT and BHC on the mud walls of human dwellings. In solid form 'Dieldrin' and 'Lindane' were the most effective toxicants against the larvæ of *Aedes aegypti* and *Culex fatigans*; in aqueous suspensions the order of efficiency was 'Dieldrin', 'Lindane', DDT. In Kenya, investigations were initiated on the metabolism of *Plasmodium knowlesi*; using the fluctuation in quantity of the adenosine phosphates as an indicator of the energy resources in the parasite–erythrocyte complex, it was found that the parasite draws upon the energy resources of the erythrocyte during its multiplication in the blood stream, and that the adenosine triphosphate and diphosphate contents vary inversely with the percentage of parasitized cells.

A detailed entomological survey to determine to what degree West African strains of *Aedes aegypti* are domestic species and therefore accessible to larvicidal control measures, and whether this species is the sole or even the most important local vector, has been commenced in and around Ilobi, a typical rain-forest belt village fifty miles from Lagos, while from the results of surveys of yellow-fever antibody in man and monkey made during the past ten years certain epidemiological patterns in south, south-west, eastern and northern Nigeria emerge.

In a study on the relation of the virus to its insect host, the East African Virus Research Institute at Entebbe has concentrated on the genetical and breeding aspect, to elucidate why only some mosquitoes are infectible; other studies at Entebbe concern the relation of virus to host tissues and the behaviour of Rift Valley fever in the mouse, while in collaboration with the Laboratoire Médicale de Stanleyville, Belgian Congo, a survey was made of yellow-fever immunity among forest pigmies. Tests of the Malayan strain of *Aedes aegypti* have shown that under laboratory conditions it is a most effective vector for the transmission of yellow-fever virus by bite. The Trinidad Regional Virus Laboratory, Port of Spain, has given full attention to yellow fever, following the isolation of yellow-fever virus from a patient from a forestal region of Trinidad; immunity surveys have also revealed that dengue is widespread throughout the island and that ilheus is widespread in the lowland high-rainfall–forest–cocoa area. In Malaya sera from six rural communities exposed to different predominant biting mosquitoes were being examined for antibodies to yellow fever and Japanese encephalitis, and a comprehensive clinical and laboratory study of acute febrile illnesses in and around Kuala Lumpur was undertaken to define their etiology and determine the part that arthropod-borne viruses might play in their causation. Study of Japanese encephalitis in Malaya was extended to a search for the natural mosquito vector, and at the Lister Institute of Preventive Medicine, Elstree, the identification of blood-meals of insects continued.

In Uganda the work on the body composition of malnourished African subjects before and after feeding with high-calorific diets of high protein content continued, and the water and protein contents of muscle obtained at autopsy and operation were investigated; studies of the hæmoglobin and serum protein of subjects living in the high (non-malarious) districts and in the lower (malarious) districts of Kigezi led to the tentative conclusion that the high values for gamma-globulin are in part due to malarial infection. Data on the potassium and sodium concentrates in the plasma of infants suffering from kwashiorkor show that plasma potassium values in children who do not suffer from severe diarrhœa are within control limits. At the Hot Climate Physiological Research Unit, Nigeria, a statistically designed investigation was made of certain variables in the standard Harvard pack test. A long series of trials began on the effect of air movement on performance, and also preliminary work on the distribution of body fluid and the composition of the body. An active programme of leprosy work at Singapore included a chemotherapeutic trial of isonicotinic hydrazide, and a study was made of the interrelationship of the Mantoux and Lepromin reactions in an attempt to evaluate the use of B.C.G. vaccine as a prophylactic in leprosy, which indicated that leprosy attacks essentially the Mantoux-negative individuals and that infection with tuberculosis resulted in some resistance to leprosy. A new mass-treatment campaign has been started in Keneba against *Microfilaria bancrofti* infection using 'Hetrazan' in conjunction with an anti-histamine drug. The search for new antibiotic-producing organisms, particularly streptomyces, from Malayan soil continues, and further mosquito infectivity experiments have confirmed that, in patients carrying gametocytes of a proguanil-resistant strain of *P. falciparum*, anopheline mosquitoes can be infected from a person taking 0·4 gm. proguanil daily. Further observations in the Kitui kala-azar area indicate that an anthropophilic species, provisionally designated *Phlebotomus* (*Sergentomyia*) sp. nov. 2, is the most likely vector of the epidemic, and experiments in Fiji indicate that the most effective dosage of 'Hetrazan' for control of filariasis is one 50-mgm. tablet taken on one day per month for twelve months.

(*To be continued*)

FOURTH NATIONAL CLAY CONFERENCE IN THE UNITED STATES

THE Fourth National Clay Conference of the National Clay Minerals Committee, United States, was held in the Department of Mineral Industries of the Pennsylvania State University, University Park, Pennsylvania, and consisted of seven sessions during the three days October 11–13. Approximately fifty-four papers were presented. Participants came from all regions of the United States, as well as seven from overseas: Dr. G. F. Walker (Australia), Dr. W. Dekeyser (Belgium), Prof. U. Hofmann (Germany), Dr. J. L. White and Dr. D. M. C. MacEwan (Great Britain), Prof. T. Sudo (Japan), Prof. J. M. Albareda (Spain). Dr. Hénin (France) was prevented by illness from attending. E. W. Radoslovich (Australia), J. Kulbicki (France), J. Zussman (Great Britain) and H. Heystek (South Africa), who were on extended visits to the Pennsylvania State University, were also present.

With such a wealth of papers, it would be difficult to give a detailed report. The present account concentrates on certain topics which seemed to me to be of importance, and is bound to be coloured by personal interests. It may, however, not be entirely a matter of personal prejudice that the study of interstratified, or mixed-layer clay minerals, appeared to emerge as one of the important growing-points of this branch of science. Their existence was reported many years ago by Alexander and others[1], and, since then, gradually increasing numbers of studies of such minerals have been appearing. At the Pennsylvania meeting, a whole session was devoted to this topic. The use of Geiger-counter recording apparatus for X-ray diffraction allows very extensive surveys to be made in a relatively short time. C. E. Weaver reported on the examination of three thousand sedimentary rocks, his conclusion being that interstratified clays are among the commonest mineral types present in the clay fraction. Systems identified are randomly interstratified illite–montmorillonite, chlorite–vermiculite, illite–chlorite–montmorillonite, chlorite–kaolinite, and regularly interstratified chlorite–vermiculite. A vermiculite–illite system, weathering to a 'chloritic' system (alumina in interlayer positions), was reported from New Zealand soils by T. Tamura. Schmehl and Jackson directed attention to the presence in soil clays of amorphous 'relicts', not giving distinct diffraction maxima, even on heating. T. Sudo reported certain Japanese acid clays which are randomly mixed kaolinite–montmorillonite; some of these minerals show almost no basal reflexions, a phenomenon which has not been satisfactorily explained. Vanadium silicates resembling clay minerals were described by J. C. Hathaway, who reported that they show mixed-layer expanding structures, mica–montmorillonite and chlorite–montmorillonite.

The name 'corrensite' has been proposed[2] for (apparently) a regular 1 : 1 montmorillonite–chlorite, and two occurrences of similar material were described at this meeting by J. W. Early and I. H. Milne. Vermiculite–chlorite systems from soil and shales were described by H. Heystek. D. M. C. MacEwan reported a Fourier-transform investigation of a mica–montmorillonite interstratified system in a Silurian clay from Worcestershire, the system being strikingly similar to the 'Kinnekulle II' clay from Sweden[3]. E. W. Tooker found mixed-layer illite–montmorillonites as stages in the series biotite–illite–montmorillonite (in an extensive paper on altered wall-rocks in the Pre-Cambrian of Colorado).

R. Roy, with his collaborators, has continued his important studies at the Pennsylvania State University on clay synthesis and equilibria, and he reported (with D. M. Roy) on hydrogen–deuterium exchange and the assignment of infra-red frequencies in clays (a caution against a too light-hearted assignment of absorption maxima to certain atomic groupings), and also on thermal transformations in dickite—namely, the formation of kaolinite by hydrothermal treatment of 'metadickite' and 'meta-metahalloysite', these substances being, of course, the analogues of 'metakaolin'. With F. A. Mumpton he has investigated the relation of ionic substitution to hydrothermal stability of montmorillonoids. Saponites are the most stable; the addition of polarizable ions (Zn^{2+}, Ni^{2+}) decreases the stability, as does the substitution of Ga^{3+} for Al^{3+} in beidellite. The interlayer ions also affect stability. Mumpton and Roy have further succeeded in synthesizing both regularly and randomly interstratified minerals.

G. W. Brindley and his collaborators have been continuing detailed structural work on clays. At the meeting, Newnham and Brindley reported on the structure of dickite, a two-dimensional Fourier investigation, which shows the octahedral layer of this mineral to have distortions of the same general type as in gibbsite (the first study of this sort on a dioctahedral mineral of the clay group); and on allevardite, confirming in general the results of Caillère *et al.*[4]. Brindley and Radoslovich have commenced a study of the hydrothermal alteration of single crystals of felspars. In Dr. Hénin's absence, Prof. Brindley also read his paper on low-temperature synthesis of clay minerals.

Other structural studies were reported by J. Zussman and G. F. Walker. Zussman proposes to divide the serpentine minerals into ortho- and clino-chrysotile, antigorite, and a third variety with orthogonal packing. (Whittaker, reporting on these minerals in November to the Mineralogical Society in London, proposed the name 'lizardite' for this variety.) Walker has investigated in detail, using two-dimensional Fourier syntheses, the dehydration mechanism in vermiculite, and his paper may well form the foundation for much future thought on clay–water relationships, replacing the earlier ideas of Hendricks and Jefferson[5]. He recognizes a two-layer stage for the interlamellar water, with octahedral co-ordination around the exchange cations; then a less hydrous stage where the cations migrate to the mineral surface, followed by a one-layer stage; and finally, as more water is removed, the 'collapsed' form without interlamellar water occurs in interstratification with the previous stage.

Walker's paper was read during a symposium on "Clay–Water Relationships", in which H. van Olphen presented experimental evidence for the magnitude of the linking force in pure clay gels (10^{-4} dynes), and the height of the energy barrier for thixotropic gelling in 0·03 N sodium chloride solution (7 kT). In the same session, D. T. Oakes and E. J. Burcik described a method for electro-osmotic charge determination in concentrated suspensions; W. H. Wood, W. T. Granquist and I. M. Krieger described viscosity measurements on very dilute suspensions; W. C. Ormsby, R. M. Witucki and W. A. Weyl reported investigations on the effect of wetting agents on deformation of kaolinite suspensions; and U. Hofmann gave experimental evidence for a relation between surface charge of montmorillonite minerals (determined by chemical analysis) and swelling properties. C. W. Marshall, who was unable to be present, sent a paper on thermodynamic, quasi-thermodynamic and non-thermodynamic methods of investigating the electrochemistry of clays.

Another symposium was devoted to "Thermal Transformations in Clay Minerals". R. A. Rowland, E. J. Weiss and W. F. Bradley reported on the study of mono-ionic montmorillonites (Na, K, Li, NH_4, H, Ca, Mg, Mn), using the 'oscillating-heating' method, which consists in continuously scanning a small diffraction region, while heating the sample. The resulting diagrams illustrate very prettily the onset and progress of reactions. J. L. White described work on the effects of molten salts on layer-lattice silicates, the most striking result being the removal of potassium from (silt- and clay-grade) mica by molten lithium nitrate, giving a montmorillonite-like product. Other papers were on the dehydroxylation of illite (B. W. Nelson), and comparison of natural and synthetic montmorillonites (L. B. Sand and M. S. Crowley).

Advances in the technique of identification of minerals were referred to by E. B. Kinter and S. Diamond, and I. H. Milne and C. M. Wardshaw (preparation of samples for an X-ray diffractometer); and by A. Auskern and R. W. Grimshaw (infra-red spectrography). Aspects of industrial interest included paper-coating by kaolinite (H. H. Murray and S. C. Lyons); green compression strengths of bentonites (W. F. Bradley); and colloidal properties of silica and silicones (E. A. Hauser).

There was no symposium on weathering and alteration of minerals, but several papers were concerned with related questions. In Illinois (H. H. Murray and R. K. Leininger), and in Wisconsin (L. D. Whittig and M. L. Jackson), illite and chlorite have been found to alter to montmorillonoid (montmorin), or vermiculite. B. N. Rolfe described surficial sediments from Lake Mead (Hoover Dam area). B. Osthaus has studied the acid dissolution of montmorillonite and nontronite, and is able to distinguish two first-order reactions in the removal of iron and aluminium (octahedral and tetrahedral co-ordination ?). G. T. Kerr, R. H. Zimmerman and F. H. Wells have found two stages in the degradation of acid hectorite, with the release first of magnesium, and then of silicon dioxide. Anion exchange was discussed by S. J. Buckwold.

The entire series of meetings gave an impressive picture of clay mineral researches in the United States at the present time. It is noteworthy that some fine pieces of research have been done by industrial laboratories, especially those of oil companies. Most of the foreign visitors seemed to find the programme over-full, and would have preferred more time. This conference represented, of course, a year's research in the field. As compared with the diversity of effort in Europe (two meetings a year in Great Britain, France and Sweden; and others in Germany, Belgium, etc.) it showed the great advantages of organization on a continental scale, enabling all the workers on the subject to get together for an intensive discussion. The result was very inspiring. The complete proceedings of the conference will appear in book form, and are at present being edited by Miss Ada Swineford, of the Kansas Geological Survey. Like the second and third conferences, they will be published by the National Research Council, Washington, D.C., as will, so it is intended, the proceedings of subsequent conferences. The proceedings of the first (Bull. 169, Calif. Dept. of Mines, 1955) and second conferences have already appeared and form attractive and valuable records of progress in this field.

THE METAPHYSICS OF SCIENCE

In the Riddell Memorial Lectures* Prof. R. O. Kapp discusses a question which is, he says, of even greater importance for science than for theology, namely, "whether non-material influences have a real existence or not" (p. 8). Kapp defends an affirmative answer to this question, a doctrine that he calls "dualism", as against the negative thesis which he describes as "monism". This nomenclature is, I think, misleading, because various theorists such as Hegel have advocated a non-material, that is, spiritual, monism. Kapp supposes not only that the two metaphysical theories of dualism and monism are answers to a genuine problem, roughly 'What are the ultimate and irreducible constituents of reality ?', but also that they are the only two possible answers to the problem. These are, of course, very large assumptions indeed, and it is regrettable that Kapp fails not only to defend them but even to state them. He gives no grounds for presenting us with what, to my mind, are equally erroneous doctrines, nor for his assumption that one must vote for one rather than the other.

Kapp regards his problem as raising an empirical issue, namely, whether or not a certain sort of entity exists. The dualism that he defends is a causal hypothesis to account for the existence of 'order' in the universe. In this sense, which we shall see is a somewhat special one, order is explicable only if there exists a non-material cause or causes; of these we are offered a generous selection: "God, the soul, entelechy, élan vitale". The generic name given to these is "diathetes". At various places they are described as "things" (p. 13), "active realities" (p. 12) and "influences" (p. 8), but it seems clear that Kapp thinks of them as entities of a kind, as he is perplexed by the problem "That diathetes, be they called God, life, mind or the soul can be nowhere and yet do things is a most puzzling concept" (p. 53). We are not told whether these "diathetes" are fundamentally one, or whether they are separate; if the latter, then criteria should be given which would enable us to decide how many diathetes there are.

---

* "Facts and Faith". By Reginald O. Kapp. Riddell Memorial Lectures. University of Durham. Pp. 63 (Oxford University Press, 1955.) 5*s*.

The argument that is advanced for the existence of diathetes is of the form of a causal hypothesis; they are said to be necessary to account for the existence of 'order' in the physical world. (It is not clear whether Kapp would regard as admissible any more direct attempt to establish their existence.) Only a certain class of physical events is the result of the causal activity of diathetes, those which occur in "living substance"; this notion is contrasted with that of the "rough untouched world of lifeless things", a phrase which recurs with hypnotic regularity. "A diathete can exercise direct control over any living substance and either only indirect control or none over all lifeless substance" (p. 17). A diathete is thus very like the driver of a motor-car—indeed this simile is explicitly used on p. 21. The crux of Kapp's argument is therefore the distinction between random and ordered events; only in living substance, he maintains, is order to be found, which is the result of 'diathetic' activity, while no such hypothesis is necessary in order to understand the processes of inanimate Nature, for these are all random.

What exactly is to be understood by the phrase 'the natural order' is, of course, a problem of the greatest importance for both philosophy and the natural sciences. Kapp recognizes the profundity of this somewhat neglected question; but his own treatment of it, so far as I can understand, is vitiated by a serious confusion. Kapp uses the words "order" and "random" as antitheses, but not always to point the same contrast. Sometimes "random" is used to mean simply "contingent"; for example, he describes the world studied by physics as "one in which anything may happen that is logically possible" (p. 36). From this quite true observation Kapp concludes in most misleading language that such a world is a 'random' one. The bounds of logical possibility are very wide, and include many concepts that are empirically *impossible*; as Russell has pointed out, there is no *logical* absurdity in the idea that the universe was created five minutes ago, complete with memories. Thus from the contingency of all factual propositions it is incorrect to conclude that there are no objective physical laws; logical and empirical necessity are concepts of quite different orders.

In denying that there is any objective order in physical nature, Kapp finds himself faced with the problem of explaining what the physical sciences are all about; if there are no laws in inanimate Nature, what are these sciences investigating? The discussion of this question is carried out with reference to Ohm's Law. Kapp argues, with some persuasiveness, that this principle should be regarded as a tautology, that is, as true by the definition of a resistance. With less plausibility this is alleged to hold true of all the laws of the natural sciences. In proposing a return to the conventionalism advocated by Poincaré some years ago, Kapp does not seem sufficiently aware of the objections that can be made against this view. Some of these are, briefly: (1) the fact that scientific laws can be represented as tautologies that are true by definition does not place them in any special category, for any proposition can be expressed as a tautology if sufficient latitude is allowed to our definitions; (2) if the principles of science are mere definitions, then it is not easy to understand how it is that scientific knowledge enables us to predict and control natural phenomena; (3) how, on such a theory, are we to explain, or even describe, the progress of the sciences? I do not deny that many, and perhaps all, scientific advances involve the re-definition of terms, but it by no means follows from this that the practice of science is to be understood as the invention of definitions.

A different use of the word 'random' can be found in those passages where Kapp contrasts it with the concept of 'ordered' as meaning the result of planning. He is much concerned to omit notions like those of 'consciousness' and 'purpose' because he believes that it is a fallacy to suppose that a diathete can operate only at a conscious level. Nevertheless, he talks as if he wishes to preserve the concept of teleology without having to face the difficulties raised by the idea of 'purpose'. Thus he compares "the extremely precise predictions that can be made in the biological sciences" (a rather paradoxical remark), with the 'predictions' about the product of the assembly line that an engineer can make from blueprints (p. 49). This somewhat special use of the word 'random' is again illustrated by Kapp's remarks about the stimuli that reach the brain. Of these he says: "They are not co-ordinated. They may arrive from anywhere. [I do not know what this means.] They are random events, unselected, most of them the result of pure chance. And yet the response of the brain to these stimuli is not random. Selection, discrimination, guidance, control do occur. Where, when, how?" (p. 20). Here 'random' clearly means 'not subject to guidance, control or selection'; and, of course, there is a perfectly good sense of the word 'chance' which means precisely this. A boy who breaks a window 'by chance' has not broken it intentionally; but this goes no way towards showing that the event in question was a chance or random event in the scientific sense, that is, inexplicable by the known laws of mechanics or psychology. The implicit teleology of Kapp's position may also be seen from the fact that he finds no incongruity in lumping together "houses, machines and living substance" (p. 36).

The concept of 'order', which is not only of great intrinsic importance but also vital to this particular argument, is unfortunately left as obscure as its antithesis 'random'. Kapp rightly believes that the notions of 'law' and 'order' are very closely connected, but he does not notice that there is here a profound ambiguity. The discussion of the conditions of order begins with a reference to human affairs. It is argued, quite correctly, that a necessary condition of order in this sphere is law "of the statute book kind". Certainly, laws of this character, such as those governing the behaviour of traffic, introduce order, in one sense of the word, into human activity. These laws "make for order", to use a phrase which often occurs in these lectures. Kapp now passes to the question whether "the laws of physics are, like those in the statute books, of the kind that make for order" (p. 23). To this question, which I shall try to show is unintelligible, Kapp returns a negative answer, on the ground that, strictly speaking, there are no laws in Nature but only the definitions and conventions established by scientists. "The precision with which experiments are repeatable does not prove that it is in the nature of matter to behave in an orderly manner but only that it is in the nature of scientists to do so" (p. 45). And again: "The place of the laws of physics, we are led to conclude, is not in the world of physical reality but in the world of scientific methodology" (p. 62, Appendix). In passing, it might be observed that from this duplication of 'worlds' one can only conclude that so far as Kapp is concerned, Carnap's "Logical Syntax of Language" and Stebbing's "Philosophy and the Physicists" have been written in vain.

The problem of whether the laws of the natural sciences 'make for order' can arise, it seems to me, only as the result of a failure to recognize the ambiguity of the phrases "law" and "law and order". The traffic laws impose orderly conduct on motorists and others, and sometimes these "statute book laws", to use Kapp's somewhat unhappy phrase, may be difficult to enforce, as in Cyprus at the present time, in which case 'the rule of law' breaks down. But this does not mean that the phenomena in question become in any way unintelligible or unpredictable from the scientific standpoint. The reason for this is that 'statute book laws' are of a fundamentally different kind from those established by the sciences. The former are *prescriptive* rules which coerce human beings to behave in certain ways because sanctions are attached to them. Of an essentially similar kind are social rules and conventions. The laws of science (including, *pace* Kapp, those of biology) are entirely unlike these, for they are *descriptive* of the actual behaviour of the subject-matter in question, whether it be human, animal or material. Hence the laws of science do not 'make for' or impose order, for only prescriptive laws are capable of this; rather, they merely record the orderly relations which obtain between events. It is worth pointing out, incidentally, that in this distinction between prescriptive and descriptive laws, first clarified by Schlick, one can find the solution, or rather the resolution, of the problem of the freedom of the will.

In the seventeenth and eighteenth centuries this issue was somewhat bedevilled by certain theorists who represented the descriptive laws of Nature (often spelt with capitals) as prescriptive laws imposed by God on the Creation. This leads to the idea that the particles of a gas are 'governed' by Boyle's Law in the same kind of way that we are governed by the income tax laws. All this, of course, arises only from a failure to notice the different senses in which words like 'govern' and 'obey' are used. If Kapp had considered this, he could scarcely have employed language like: "Only on the reason why a particle of matter implicitly obeys the laws of physics may there be difference of opinion between a theologian and his atheistic opponent. The theologian might say it was because matter does not possess free will and cannot therefore sin against God's moral law. The atheist might object that the laws of physics were not ordained by God but by Nature and that a particle of matter obeys them implicitly because it is made in Nature's image and cannot do otherwise" (p. 28). The essential point is that the laws of Nature were not ordained by anybody, so that fortunately we do not have to speculate as to what can be meant by saying that something is 'made in Nature's image'. I conclude that Kapp is right in denying that scientific laws are prescriptive, but that his reasons for this are not convincing because he fails to see that there are perfectly good laws of another, that is, descriptive, kind. If this is admitted, then it appears that Kapp's notion of order, as it concerns the natural sciences, is misconceived, and so are his attempts to find its source in 'diathetes'.

C. K. GRANT

CENTENARY OF THE FORMER SCOTTISH METEOROLOGICAL SOCIETY

THE year 1855 saw the foundation of the Meteorological Office and the Scottish Meteorological Society, both as a result of the international conference on the meteorology of the sea held at Brussels in 1853, and the centenary of the Society's foundation was celebrated at a meeting of the Scottish centre of the Royal Meteorological Society held in Edinburgh on October 28. The principal address was delivered by Sir Ernest Wedderburn, honorary secretary of the Scottish Meteorological Society during 1909–20 and now vice-president for Scotland of the Royal Meteorological Society, and a summary of the address has been published in the November number of *Weather*.

Sir Ernest began by pointing out that it was Sir Henry James, then of the Scottish Ordnance Board, who proposed the formation of the Society as the best means of making available for public use the meteorological observations held by the Northern Lights. The first Council included Thomas Stevenson, designer of the Stevenson thermometer screen, and the first secretary, Dr. Stark, organized on a standard basis the work of seventy voluntary observers in Scotland and the subsequent publication of their observations by the Registrar-General. Unfortunately their preparation for publication soon had to be given up and was performed by the Astronomer-Royal for Scotland from 1858 until 1893, when it returned to the Society. In 1860, Alexander Buchan, later famous for his world climatological atlas and his work on the climate of Edinburgh, was appointed secretary, and he soon made his influence felt by arranging in 1864 for the publication of the Society's *Journal*, which flourished until 1920. He represented the Society at the Leipzig conference of 1872 and, with the Director of the Meteorological Office, the British Government at the Vienna conference of 1873 which did much to draw up an international code of practice in meteorological observing.

Interest in observations at high levels began early in the Society's life, and before 1870 three stations were in operation at above a thousand feet. The most famous single work of the Society, the making of observations on the summit of Ben Nevis, was first mooted in 1877; the observatory on the summit was opened on November 28, 1883, and hourly observations were begun and telegraphed to the Meteorological Office in London over a line laid down the mountain. In 1883, too, the Society set up a marine research station at Granton, at which Dr. R. H. Mill began his meteorological career.

Some government grant was received to assist the Society's work, but by the early years of this century the Society had been financially exhausted by the efforts to maintain the Ben Nevis observatory, which had, unhappily, to be closed in 1904. Negotiations with the Government resulted in 1912 in the granting of an annual sum of £350 from the Meteorological Office on condition the Society maintained an office in Edinburgh to provide for public service under the guidance of a committee, of which Sir Napier Shaw, director of the Office, was appointed chairman. Financial difficulties after the First World War led in 1920 to the complete taking over by the Meteorological Office of the Society's office and its public responsibilities, and at the same time an official Meteorological Advisory Committee for Scotland was set up with the director of the Office as chairman and a membership of representatives of the Scottish universities, learned societies and government departments.

The purpose of the Society, to establish meteorological work in Scotland on a permanent and comprehensive basis, having been achieved, the Society amalgamated in 1921 with the Royal Meteorological Society, which since 1944 has had as one of its honorary officers a secretary, more recently a vice-president, for Scotland. The balance of the funds was used to found the Royal Meteorological Society's Buchan Prize for meteorological research. Meetings of the Royal Meteorological Society were held in Scotland in 1921 and 1954, and a flourishing Scottish Centre was formed in 1946. Some famous names in meteorology connected with the Scottish Meteorological Society have been mentioned. To them may perhaps be added that of C. K. M. Douglas, who joined the Society in 1916 and published his first paper, on weather observations from aircraft, in the *Journal* the same year.

INTERNATIONAL REVIEW OF EDUCATION

THE problems of educational theory and practice, of educational psychology and sociology, of education in home, school and society, have become, more than ever before, matters of international concern. National educational systems and national educational ideas can no longer safely be developed without contact with educational thought and action elsewhere in the world. The maintenance of cultural life has ceased to be something to be guided by ideals purely national in scope.

For these reasons a new educational journal designed to provide an international forum and to promote international exchange of information does not require extended justification. The *International Review of Education* has been launched on behalf of the Unesco Institute of Education, Hamburg, and edited by Karl W. Bigelow of New York, Roger Gal of Paris, M. J. Langeveld of Utrecht, Walther Merck of Hamburg and Friedrich Schneider of Munich. Editorial consultants have been appointed in various countries throughout the world and include such well-known names as Prof. C. H. Dobinson, Prof. M. U. C. Jeffreys and Prof. F. J. Schonell.

One aim of the new journal will be to inform readers as to educational theory and practice in various countries. Another—and perhaps the more important—will be to explore the extent to which such ideas and activities have elements of validity that transcend national boundaries. Such exploration will, of course, require continuing discussion and debate.

In pursuance of its aims the *Review* hopes to develop an ever-strengthening chain of contacts with educational research and training centres throughout the world. Systematic attention will also be paid to international educational conferences and congresses, as well as those of more limited scope which possess special international interest. From the torrent of educational publications appearing everywhere it is the intention to select those of outstanding extra-national significance for critical examination.

The first four numbers of the journal have now appeared, and each contains articles in English, French and German; articles in one of these languages contain useful summaries in the other two. Besides articles by leading English educationists, the first volume of the journal contains a valuable account of the reforms in the French educational system since the War; a bird's-eye view of education in India; a description of educational reform and its problems in post-war Japan; two articles of different points of view on nationalism and internationalism; a survey of political education in France, Great Britain, Germany and the United States; a penetrating inquiry into the state of American education and its relation to politics; a comparison between "le français élémentaire" and basic English which suggests the latter may be too basic; and an interesting account of the way vocational training in Germany has been humanized.

SOURCES OF ANIMAL BEHAVIOUR

IN his inaugural address, delivered on May 5, 1955, at University College, London, and recently published*, Prof. G. P. Wells has drawn forcible attention to the importance of spontaneous rhythms in animal behaviour. His analytical studies of the lugworm *Arenicola* over the past twenty years have shown how little the normal behaviour of this worm seems to depend on the reflexes of a passive animal and how much depends on inherent rhythmic activity. Burrowing, feeding, defæcation and respiration are controlled by 'physiological clocks'. There is rhythmic activity originating from the œsophagus, and this itself recurs in outbursts controlled by rhythms of a higher order.

In any species there are many patterns of these rhythms, and the animal may pass abruptly from one pattern to another. These patterns vary with the species; and the different patterns of rhythms are recognizably characteristic of each species, quite as much as are the anatomical characters by which they are distinguished systematically.

To illustrate the generality of rhythmic patterns, Prof. Wells shows that, just as in his *Arenicola*, much recent work on the behaviour of birds suggests that this is governed by a variety of spontaneous rhythms—that is, regular activity not directly related to environmental stimuli. Rhythmic outbursts of song, feeding and reproductive cycles of behaviour recall the spontaneous rhythms of the worms. It is true that bird behaviour differs from worm behaviour in its much greater complexity and in the much greater indirect influence of external stimuli upon the rhythms and their patterns. But the fact remains that much that is most characteristic of the behaviour of both worms and birds depends on highly individual patterns of rhythmic activity apparently of internal origin.

---

* The Sources of Animal Behaviour. (An Inaugural Lecture delivered at University College, London, 5 May, 1955.) By Prof. G. P. Wells. Pp. 20. (London: H. K. Lewis and Co., Ltd., 1955.) 2*s*. 6*d*.

The address is stimulating and leads one to many questions. What are these 'clocks' that control rhythmic behaviour? When we consider rhythmic contractility, on one hand, and reproductive cycles, on the other, it is clear that the clocks work on very varied principles. The one common feature is the rhythmic activity of the system whatever its grade of organization. Possibly it is a general character that they are systems in relaxation oscillation. Living organisms are dynamic, and it does not follow that they will naturally tend towards a constant steady state. Indeed, in many cases such steadiness is only achieved by the evolution of elaborate controls—as the proprioceptive machinery of limbs. Systems in relaxation oscillation may arise at many different levels of organization. Once they are there, they may inevitably be built into the behaviour of the organism through the operation of natural selection.

USE OF LOGARITHMIC NOTATION IN SCIENCE AND ENGINEERING

By Prof. S. DEVONS, F.R.S.
University of Manchester

FOR the past ten or twelve years I have been using, and encouraging colleagues and students to adopt, a logarithmic system of notation, in place of the conventional arithmetical one, as the normal one in which to express physical magnitudes and relations. Suggestions that logarithmic scales and units be used more widely have been made by numerous writers, and such systems have obvious advantages. The experience gained in the use of a general system of this sort confirms that the advantages are substantial, perhaps more than is generally appreciated, and that they definitely outweigh its drawbacks and are sufficient to justify its more widespread use.

A large proportion of statements in physical science are in the form: the quantity X, as measured (calculated), is n times a specified unit. The number n is not normally integral or exact. It is not arrived at by counting but by computation from primary physical measurements (empirical quantities), and in this process of computation multiplication plays a dominant part. One can see that this is the case by inspecting a typical table in a compilation of physical data, such as fundamental constants[1], electrical resistivities of metals[2], wave-lengths of X-ray lines[3] or abundances of isotopes[4]. One will find, normally, that the numbers are spread roughly uniformly over a limited logarithmic scale: for example, about 30 per cent of the entries will have the first significant figure 1, whereas only 5 per cent will begin with 9. (Even when the primary quantities are not 'logarithmic', the quantities derived after a few multiplicative steps soon tend to be so.)

The fact that most, although not all, of the quantities used in physical expressions and calculations are of this 'logarithmic' sort suggests that the normal notation to be used in expressing them, and numerical relations between them, should also be logarithmic, with some convenient unit of relative magnitude. A very convenient unit that has long been used in several branches of physics and engineering to denote a ratio of powers is the decibel ($10^{1/10}$, or approximately a factor 1·2), and many proposals have been made to adopt it (either with the same or a new name) for wider use. For the quite general use proposed in this article, a simpler and more distinct name and notation is called for. I have used the term 'jot' for the unit, and I have found the notation $x =$ (unit $\pm$ $xyz.ab$) jot, with the word 'jot' normally omitted, to be simple and unambiguous. It readily permits the simultaneous use of logarithmic and normal notation. Thus, for example, electron charge = (e.s.u. $-$ 93·2), velocity of light = (cm./sec. + 104·8), to an implied accuracy of $\pm$ 0·05 jot (or about 1 per cent). No confusion arises in addition, subtraction, etc.; for example, (c.g.s. + 82·1) + (c.g.s. + 86·2). A notation such as this which emphasizes the unit has considerable pedagogic value. Some other advantages of the logarithmic notation are as follows.

Simplicity of calculation. Just as so many of the physical quantities one deals with are 'logarithmic', so, naturally, the arithmetical manipulations in which they are involved are predominantly multiplicative (including roots, powers, reciprocals). These manipulations become, obviously, greatly simplified and far less liable to error if one starts, works and finishes with the quantities expressed in logarithmic notation. Of course, addition and subtraction become more complicated, but since these operations normally involve quantities of the same order of magnitude, whereas multiplication often involves many orders of magnitude, it is advantageous to have the notation suited to the more frequent and important operation.

Economy of notation. As previously indicated, ordinary arithmetical notation does not use all the digits equally when dealing with usual physical magnitudes. Less digits are required, on the average, to indicate a specified accuracy on the logarithmic scale. This, coupled with the simpler notation, makes quantities expressed logarithmically easier to write, remember, and particularly to manipulate mentally. Compare, for example, $m = 1 \cdot 67 \times 10^{-24}$ gm. with $m =$ (gm. $-$ 237·8), which has three less digits, and all the digits are on a similar footing.

Another feature of the logarithmic system is the possibility of 'normalizing' the scale of measurement so that a high accuracy can be expressed with few digits. For example, the specific gravity of a liquid might be expressed as (unity + 0·2), with an accuracy of 1 per cent, whereas normally this accuracy would require three digits.

Simplification of units. An expression such as $a_0 = 5 \cdot 292 \times 10^{-9}$ centimetres (Bohr radius) is clearly both inconsistent and uneconomical in its notation. First, we have a mixture of logarithmic and linear notations: the digits themselves are linear; whereas the decimal, exponent of 10, and the prefix centi- are all logarithmic, and all three doing the same job. With a consistent logarithmic notation such as the one proposed, multiplication even by large powers of ten does not result in clumsy expressions, so that the need for many units differing by powers of 10 is largely obviated.

For example, suppose we are making (mental) calculations to an accuracy of about 10 per cent, so that we work to the nearest jot, with mean individual error of 5 per cent. Then with four hundred three-digit numbers and ± signs we cover the range of magnitudes 10^{80} to 1, sufficient for most purposes. Moderately accurate calculations can be made in any system of units, and the task of memorizing physical data is made significantly easier. For example (to an accuracy of $\frac{1}{2}$ jot), r_0 (classical radius of electron) = (cm. − 126). Using c = (cm./sec. + 105) and year = (sec. + 75), we get r_0 = (light-year − 306), which is scarcely more difficult to deal with than (metre − 146) or (angstrom − 46). With a notation that can express the size of the electron as conveniently in light years as in angstrom units, there is little need for a large multiplicity of units (and especially of length). The use of a single unit in all branches of physical science would not only simplify many calculations, but it would also bring out, most directly, the relative magnitudes of different physical quantities, related and otherwise.

Representation of errors. In logarithmic notation the sign and the number of digits before the decimal point indicates the magnitude; that after, the precision. Without further specification, no digits after the point indicate an average accuracy of ± 5 per cent, one digit ± 0·5 per cent, etc. For normal error distributions, the accuracy can be given directly and absolutely by additional figures (for example, superscripts) giving the size of error in units of last digit written. (The ± sign is redundant, and more than one figure is seldom required.) For example, c = (cm./sec. + $104{\cdot}77^{2}$) would indicate an accuracy of the quoted value of 0·02 jot or about ± 0·4 per cent.

The systematic use of logarithmic notation does involve transcription into this notation of quantities such as meter readings, some numerical constants, and data presented in conventional form. The most frequent of these is the last-mentioned, and this task would be avoided if the notation were generally used and accepted. The incorporation of non-dimensional constants presents no difficulties; for example, the expression 4π(e.s.u. − 82·5) is quite unambiguous and, moreover, displays the nature of the quantities involved very directly. Fortunately, π and powers of 2 can be expressed quite accurately in integral units (jots), and even '137' can be replaced by 21·37 to an accuracy of one or two parts in a thousand! Primary observations fall into two groups: some, such as micrometer or thermometer readings, involve counting and additive operations; others, such as most electrical instruments, do not, and there is much to be said for having the scales of these latter marked in both logarithmic and linear fashion.

To summarize: the use of logarithmic systems simplifies notation and calculation, eases the burden on memory and reduces the need for a multiplicity of units. Whenever I have had occasion to propound the merits of the system, I have generally found ready acceptance of the points made here, and this leads me to propose general use of some such system.

SONIC SCATTERING LAYERS OF HETEROPODS

By M. BLACKBURN

Division of Fisheries, C.S.I.R.O., Cronulla, New South Wales

DURING a nineteen-day oceanographic cruise in April 1955 in Bass Strait, southern Australia, the Fisheries Research Vessel *Derwent Hunter*, using a 14-kc./s. echo-sounder (Kelvin Hughes MS 24*E*), repeatedly detected sonic scattering layers over a large and well-defined area of continental shelf. The layers were diffuse and quite unlike fish traces, and varied greatly in density; they were virtually confined to the top 20 m. of the sea and were generally found in the upper 10 m., by both day and night.

Fig. 1 shows the track of the ship, distinguishing the long echo-sounded portion; the stations at which plankton was collected; and the sections of the track along which the layers were found, which were all east of 145° 15′ E. long. The longest section over an unbroken layer was about seventy miles.

Fig. 2 shows a portion of the echogram record of the densest of these layers, taken just before and during the occupation of one of the stations (No. 1 in Fig. 1), on a calm night.

Vertical bottom-to-surface hauls were made in duplicate with the "Discovery" *N*70 plankton net at each station on the continental shelf, and similar paired hauls from 500 m. to the surface were made at each station on the continental slope. Echo-sounding was done at twenty-seven stations, fourteen at which layers were detected and thirteen at which they were not, and was omitted at fourteen stations (mostly on the continental slope).

The plankton catches were checked to try to identify some organism which (*a*) was present at each station at which a scattering layer was found, and (*b*) was absent at each station at which no layer occurred. No organism completely satisfied these conditions, but three species met them closely: the cladoceran *Evadne nordmanni* Lovén, the lancelet *Paramphioxus bassanus* (Gunther), and the heteropod mollusc *Firoloida desmaresti* Lesueur.

Evadne nordmanni was absent at one station where there was a scattering layer, and present at three stations, including one as far west as 143° 15′ E. long. (No. 4 in Fig. 1), where there was no layer. This species is most unlikely to have caused the echo-sounder traces because it is very small (about 0·5 mm. long) and was not very abundant at any

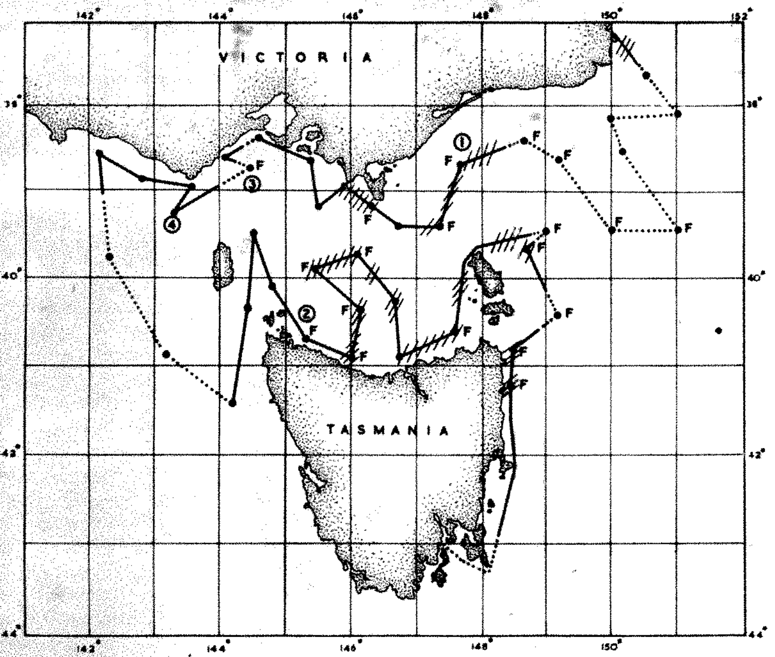

Fig. 1. Chart of the cruise showing the echosounded (——) and un-echosounded (· · · ·) portions of the track, and station positions (●). The occurrence of the scattering layer is indicated by hatching, and of *Firoloida* (in plankton catches) by the letter *F*. For further explanation see text

station. At the station to which Fig. 2 refers, for example, only about two hundred individuals were taken in two vertical hauls.

Paramphioxus bassanus was absent at four stations where there was a layer, including the station to which Fig. 2 refers, and present at three stations where there was no layer. The greatest density was observed at one of the three latter stations, and elsewhere the numbers did not exceed ninety-one for a pair of vertical hauls. The animals were only about 5 mm. long, and as lancelets are benthic forms it is most unlikely that the scattering layer consisted of this species.

Firoloida desmaresti was taken at eleven of the fourteen stations where there was a layer and at one of the thirteen stations at which there was no layer. The best catch, nineteen for a pair of vertical hauls, was made at the station to which Fig. 2 refers, where the scattering layer was densest. The average length of the specimens was about 40 mm., diameter 4 mm., and volume 0·4 ml.

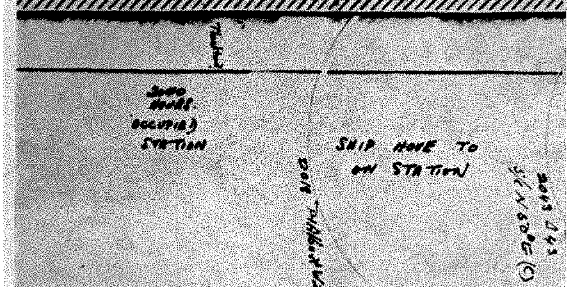

Fig. 2. Portion of echogram showing the appearance of a dense scattering layer before and during the occupation of a station (No. 1 in Fig. 1). Note time scale in minutes above. Depth of water 75 m., with layer confined to upper 20 m.

According to Tesch[1], *Firoloida desmaresti* is given to swarming, and the members of the family to which it belongs, the Pterotracheidae, are active and fast-swimming. This could explain why larger numbers were not captured and why the species was not taken at all at three stations at which a scattering layer was seen: the animals might have avoided the net. Fig. 2 shows some discontinuity of the layer beneath the ship while she was on the station, which could be due to disturbance of the animals by the raising and lowering of nets. A re-examination of the echograms at the three above-mentioned stations showed that the layer was faint or absent at the actual times the plankton nets were used, at two and possibly all three stations.

One specimen of *Firoloida* was taken in two hauls at one station at which the echo-sounder revealed no sign of a layer (No. 2 in Fig. 1); and here, just beyond the western boundary of the general area of the scattering layer, it may be assumed that the numbers were insufficient for the formation of a detectable layer. The same might have been true of another station still farther to the west (No. 3 in Fig. 1), where only one specimen was taken in two hauls, but there was no echo-sounding at this position.

Thus *Firoloida*, by virtue of its size, habits and distribution in relation to that of the scattering layer, is far more likely to have been the constituent of the layer than any other organism sampled by plankton nets. There remains the possibility that the layer consisted of some animal which avoided the nets on every occasion. Such an organism would probably be one of the smaller members of the nekton, such as a small fish or cephalopod. However, the nekton of this region is fairly well known from a study of the stomach contents of the omnivorous pelagic scombroid fish *Thyrsites atun* (Euphrasen), which I am studying, and only one nektonic species apart from *Thyrsites* itself has been found to occur in abundance in Bass Strait at the time of year in question. This is the anchovy, *Engraulis australis* (White), which gives echogram traces of a very different kind. *Thyrsites* itself has not yet been found to give any well-marked echogram trace, and its distribution at the time of year under discussion is generally coincident with that of the euphausian *Nyctiphanes australis* Sars, on which it preys; and *Nyctiphanes*, on the cruise of April 1955, was most abundant to the west of the region of the scattering layer.

The sonic scattering layer described may therefore be attributed to the swarming of the pterotracheid heteropod mollusc *Firoloida desmaresti* Lesueur. The swarming was probably for reproductive purposes, as many females had egg chains.

The work described was part of the research programme of the Division of Fisheries, C.S.I.R.O., Australia. Mr. W. Dall, of that Division, identified the plankton of the cruise. [Oct. 14

Sensitivity of the Mouse Testis to the Mutagenic Action of X-Rays

In making estimates of the damage caused by exposure of human gonads to ionizing radiation, it is essential to take into consideration variations in sensitivity of the germ cells at different stages in their development. In *Drosophila*, this has been done by mating irradiated males to a succession of females and determining mutation-rates separately for successive broods[1]. It was found that spermatids, probably at the stage of transformation into spermatozoa, are the most sensitive stage; mature spermatozoa are one-third or one-fourth as sensitive as spermatids, and spermatocytes are intermediate. Spermatogonia are the least sensitive: a given dose of X-rays produces only one-third to one-half as many mutations in spermatogonia as in spermatozoa.

This last point is of particular significance for estimates of radiation damage in man. In a human population exposed to chronic irradiation, spermatogonia form the majority of treated cells, and it is their sensitivity which in the main determines the genetical effectiveness of the exposure. As extrapolation from *Drosophila* to man seems hazardous, it would be of the greatest value if the 'sensitivity pattern' of the testis could be established for a mammal, for example, the mouse. Unfortunately, the most important comparison—that between spermatozoa and spermatogonia—requires scoring of genetical effects which are not subject to germinal selection during and before meiosis, and this rules out the two most frequent effects in the mouse, namely, dominant lethals and translocations. These can, however, be used for comparing the sensitivity of post-meiotic stages. If the post-meiotic sensitivity pattern of the mouse testis should resemble that of the *Drosophila* testis, we may with some confidence extrapolate to pre-meiotic stages and predict that in mammals, as in *Drosophila*, spermatogonia will be less sensitive than spermatozoa.

Hertwig[2] and Russell *et al.*[3] compared the frequencies of dominant lethals in litters produced during the early and late part of the pre-sterile period; they found significantly higher frequencies in the late litters. This suggests that in the mouse, as in *Drosophila*, X-rays produce more genetical changes in spermatids than in mature spermatozoa. We have carried out a pilot experiment to test this conclusion for translocations.

Five wild-type males from crosses between inbred lines were exposed to X-ray doses varying from 400 to 600 r. Each male was given five females, and every morning females which had copulated during the night were replaced by new ones. All sons which had been conceived during the pre-sterile period were tested for fertility by mating to several (two to six) females which had had litters of seven or more young by untreated males. Sons of treated males which produced average litter sizes of less than nine were suspected of semi-sterility and were examined cytologically for translocations. Twenty separate chromosomal elements seen in at least five metaphase plates of the first meiotic division were taken as evidence for the absence of a translocation. The consistent presence of nineteen separate elements served as indication for the presence of a translocation. Table 1 shows the strong correlation between low fertility and a cytologically detectable translocation.

TABLE 1

Average litter size	No. of males examined cytologically	Translocation present	Translocation absent
0	2	2	0
6	18	18	0
6–6·8	8	2	6
7–8·9	3	0	3

Males with average litter sizes of nine or more were not examined cytologically. This may result in the loss of small translocations which do not cause lethal aneuploidy of the zygote. In fact, one male with average litter size nine, which was examined because it had produced two litters of seven, carried a translocation involving an exchange of minute segments, so that, in one out of six cells examined, nineteen chromosomal elements were present. This case was not included among the translocations, since similar small translocations may have been present in fertile males which were not examined cytologically. One of the highly sterile males carried a complex interchange which was scored as two translocations. No controls were used, for the occurrence of spontaneous translocations in mice must be exceedingly rare. No translocation was found in 248 *CBA* males which one of us (B. M. S.) had examined previously, and none has been reported in the literature.

Table 2. NUMBERS OF TRANSLOCATION HETEROZYGOTES AMONG F_1 MALES

Litter number	Mouse 1	2	3	4	5	Trans.	Total animals	%
1	1/4	1/5	1/5	0/5		3	19	15·8
2		1/3			0/2	1	5	20·0
3	1/7	1/5	0/5	0/2		2	19	10·5
4	0/2	1/4	1/5	0/3	0/3	2	17	11·8
5			0/2	3/4	0/3	3	9	33·3
6	2/2	0/1	2/5	0/1	0/1	4	10	40·0
7	1/6	1/3	1/2		1/5	4	16	25·0
8		0/2	1/2		0/3	1	7	
9					2/2	4{ 2	{ 2 }	25·0
>9			1/7			1	7	
	4/21	5/23	8/33	3/15	3/19	23	111	

In Table 2 the full results are presented. In the last column the overall translocation frequency has been calculated for each litter number, and these figures have been plotted in Fig. 1.

It will be seen that after the fourth litter translocation frequency rises to a higher level, which is more or less maintained to the end of the pre-sterile period. If the slight decrease in the last litters is more than an effect of chance variation, it may be assumed that the sperm used for these litters could be traced back to irradiated spermatocytes, in which

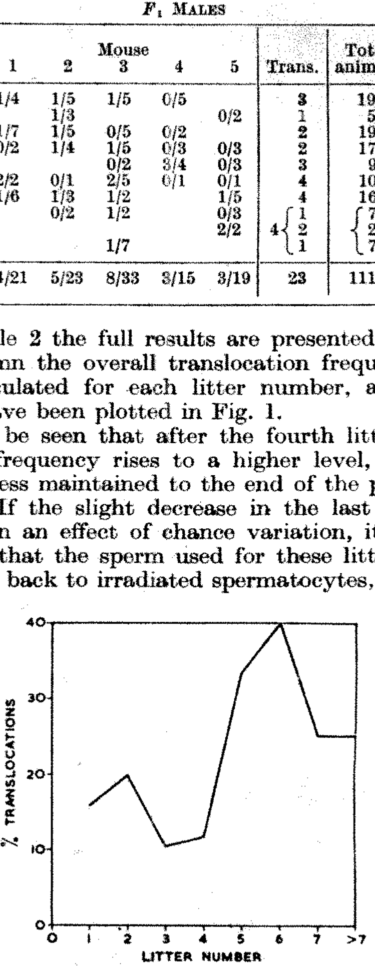

Fig. 1. Translocation frequency in successive litters

germinal selection has started to operate against translocations. Altogether, there were eight translocations in sixty males from the first four litters, as against fifteen in fifty-one males from later litters. The difference has a probability of slightly less than 5 per cent of being due to sampling error. For a more elaborate statistical analysis the present results are too scanty. Confirmation on a larger scale is desirable, but cannot be obtained with our present facilities. We hope to be able to provide it at some later time.

Meanwhile, the results presented here, together with Hertwig's[2] and Russell's[3] previously mentioned findings on dominant lethals, offer presumptive evidence for the conclusion that in the mouse, as in *Drosophila*, spermatids are more sensitive to the mutagenic action of X-rays than mature spermatozoa.

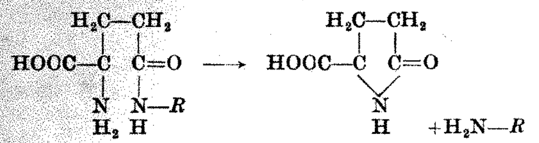
Enzymic Formation of Pyrrolidone Carboxylic Acid from γ-Glutamyl Peptides

Pyrrolidone carboxylic acid has been reported frequently as a constituent of biological systems. Ellfolk and Synge[1] have summarized these reports and clarified the reliability of methods used for its identification. Pyrrolidone carboxylic acid can be formed rather readily from glutamine, γ-glutamyl peptides, and even glutamic acid in non-enzymic reactions, and in some cases this may account for its reported natural occurrence. For example, Woodward and Reinhart[2] claimed that an enzyme from kidney, later characterized as γ-glutamyl transpeptidase[3], caused the formation of varying amounts of pyrrolidone carboxylic acid from glutathione ; but the results of Hird and Springell[4] suggest strongly that the pyrrolidone carboxylic acid isolated by these authors resulted from secondary non-enzymic breakdown of γ-glutamyl peptides under the drastic conditions applied.

In the present work an enzyme has been isolated from liver tissues which does in fact catalyse the formation of pyrrolidone carboxylic acid from glutathione and other γ-glutamyl peptides in accordance with reaction 1 :



(1)

This enzyme is quite distinct from γ-glutamyl transpeptidase. It is very active in rat liver, in which tissue the transpeptidase occurs in traces only ; and when the two enzymes occur together, as in pig liver, they can be separated cleanly by centrifugal fractionation followed by fractionation with ammonium sulphate. Furthermore, highly active preparations of γ-glutamyl transpeptidase, after appropriate purification, fail to produce even traces of pyrrolidone carboxylic acid detectable by the methods used here.

It is proposed to refer to the pyrrolidone carboxylic acid-forming enzyme as γ-glutamyl lactamase. It will be noted that the cyclic lactam is formed by transfer of the γ-carboxyl group of the glutamyl residue from the peptide linkage to new linkage with the amino-group of this same residue. The enzyme has been shown to act upon γ-glutamylglycine, γ-glutamylglutamic acid, γ-glutamylphenylalanine and glutathione—more slowly upon the last two substrates. The enzyme has no action on glutamine or on free glutamic acid.

In all cases tested the γ-glutamyl peptides are converted completely (within the limits of detection) into pyrrolidone carboxylic acid plus the C-terminal amino-acid or peptide. The purified enzyme is devoid of hydrolytic activity and no free glutamic acid appears during its action. No reversal of the reaction shown in reaction 1 can be demonstrated when the enzyme is allowed to act upon pyrrolidone carboxylic acid plus amino-acids, even when they are present in high concentration ; the equilibrium seems to lie far to the right. No pyrrolidone carboxylic acid is detectable when boiled enzyme is incubated with a γ-glutamyl peptide under the usual conditions.

The γ-glutamyl lactamase may be prepared from pig liver in partially purified form as follows : (i) liver tissue, in 3-gm. portions, is macerated in a glass pestle homogenizer in 25 ml. 0·25 *M* sucrose solution ; (ii) the homogenate is centrifuged at 105 × gravity in a 'Spinco' centrifuge (model *L*) for 30 min. at 0° C. ; the supernatant liquid is dialysed against frequent changes of distilled water in the cold ; (iii) the dialysed solution is treated with 2·33 vol. saturated ammonium sulphate solution at *p*H 7·0 and 0° C. (to give 0·7 saturation). After 1 hr. the precipitate is removed and discarded. The supernatant solution is now brought to 0·85 saturation by addition of solid ammonium sulphate. The resulting precipitate is removed on the centrifuge, dissolved in 1/20 of the original volume of water, and the solution is dialysed against distilled water.

During this procedure, a purification of about twenty-fold is achieved. The bulk of the γ-glutamyl transpeptidase is removed in step (ii), and the small amount of this enzyme remaining at the end of step (ii) is removed completely in step (iii).

The action of the enzyme has been studied by chromatography on paper. Samples taken at intervals from enzymic reaction mixtures are killed by heating in boiling water for 1 min. in sealed capillary tubes. (Under these conditions glutamine breaks down to form pyrrolidone carboxylic acid, but no formation of the acid from the different γ-glutamyl peptides used could be detected.) Portions of these samples are spotted on to phosphate-treated chromatograms (No. 3 Whatman paper is dipped into 0·03 *M* sodium phosphate buffer at *p*H 6·7 and dried). The chromatograms are developed using propanol–buffer (80 v./20 v.) as solvent. In this system all constituents of such reaction mixtures (γ-glutamyl peptides, the resulting free amino-acids, and pyrrolidone carboxylic acid) are separated cleanly and reliably. Pyrrolidone carboxylic acid is detected on the chromatograms by means of the chlorine–starch–iodine method[5] as suggested by Ellfolk and Synge[1].

The γ-glutamyl lactamase activity is measured from the chromatograms by the initial rate of liberation of glycine from γ-glutamylglycine, using the method described elsewhere[6]. For this assay the reaction mixture contains 0·05 mole γ-glutamylglycine, 0·10 mole lithium borate buffer of *p*H 8·0, and usually 50 μl. enzyme solution, the final volume being 200 μl. The presence of γ-glutamyl transpeptidase together with the lactamase is indicated by the formation of the tripeptide γ-glutamyl-γ-glutamylglycine, the course of formation of which may also be followed quantitatively. (The tripeptide runs more slowly than γ-glutamylglycine, whereas glycine and pyrrolidone carboxylic acid run more quickly.)

There have been clear indications for many years that pyrrolidone carboxylic acid is metabolized actively in the animal body[7], and some authors have postulated that it may take the role of an intermediate between glutamic acid and the amino-acids known to be derived from it in the body. Up to the present, however, the evidence has not supported this hypothesis[8]. The demonstrated occurrence of the γ-glutamyl lactamase focuses attention once more upon the interesting problem of the fate of pyrrolidone carboxylic acid in the body since, so far as is now known, this new enzyme catalyses specifically the formation of pyrrolidone carboxylic acid from a common cellular constituent (glutathione) or from other γ-glutamyl peptides which are derived from it in known enzymic reactions.

The programme of which this work forms a part has been supported generously by the J. P. Bickell Foundation. One of us (G. E. C.) held a Fellowship from the National Research Council of Canada, which has supported the work in other ways. We acknowledge our indebtedness to these bodies.

Paramagnetism of a Reduction Product of Vitamin B_{12}

The fact that vitamin B_{12} is diamagnetic indicates that the cobalt atom in the molecule is trivalent[1]. It can be assumed that it is at a lower valency state in at least some of the products which have been obtained from vitamin B_{12} by reducing agents[2,3]. This has been confirmed by polarographic measurements[4]. However, so far as we know, a direct determination of the valency of the cobalt atom in a reduction product (for example, by magnetic methods) has not been done hitherto.

We began susceptibility measurements on the reduction products of vitamin B_{12} in order to obtain further information on the valency of the cobalt atom in vitamin B_{12} itself, which has been discussed again recently[5]. Furthermore, magnetic investigations, such as have been carried out with hæmoglobin[6] and the catalases[7], seemed desirable since vitamin B_{12} and those substances show structural analogies[8].

The magnetic investigation of vitamin B_{12} presents difficulties, since the starting material is available only in small amounts and the reduction products are unstable. After having developed a micro-method, which was applicable to this special problem and enabled us to work with 100–500 μgm., we were able to show that the reduction product, which has been previously described by Schindler[3], is paramagnetic. An approximate figure for its susceptibility was also determined.

Schindler's[3] procedure, which was adapted to microscale working, was followed. 2–5 mgm. of vitamin B_{12} is dissolved in 500 μl. of 10 per cent aqueous ammonium chloride solution. 60 μl. of this solution is made to react in a sealed tube (100 μl.) with zinc dust (very pure) in a nitrogen atmosphere. The zinc dust is distributed in the solution by rotating the tube. The solution turns brown at first, finally weak greenish-violet or almost colourless. (Schindler mentions a blue colour, but he worked with bigger layers of substance.) The zinc dust is centrifuged off, and the change in susceptibility caused by the reduction is determined immediately. Even in the absence of air the solution is not stable, as can be seen from the colour changes.

The change of susceptibility was determined by our method of 'magnetic balance' (to be described in detail elsewhere). First, the unreacted original solution is 'balanced'. A small sample tube, which holds 40 μl., is filled with this solution and then introduced into a vessel containing cobalt sulphate solution placed between the poles of an electromagnet. When the field is applied, a force is exerted upon the tube, which depends on its mean susceptibility and the susceptibility of the cobalt sulphate solution. Since cobalt sulphate is paramagnetic and water diamagnetic, these forces (for a fixed position of the tube) can be made to balance by varying the concentration of the solution. We then refer to the tube, including contents and solution, as magnetically balanced. After that, the above procedure is repeated with a reduced sample of the same solution. Now the concentration of the 'balancing solution' has to be increased. Consequently the contents of the tube has become more paramagnetic because of the reduction. The change in susceptibility can be calculated from the change in concentration of the balancing solution.

The 'magnetic balance' is determined as follows. The sample is attached to a Cartesian diver, and the whole system is balanced hydrostatically in the cobalt sulphate solution. With this arrangement we have a very sensitive instrument for detecting whether or not the sample tube is magnetically balanced. When the field is applied, movement will occur unless the balancing has been achieved.

One of our solutions contained 3·6 mgm. vitamin B_{12}/ml. (Therefore there were 144 μgm. vitamin B_{12} in the sample tube.) The concentration of the balancing solution (volume 56 ml.) before the reduction was 6·65 mgm. cobalt sulphate per ml. After reduction, another 0·15 ± 0·01 ml. of a solution containing 50 mgm. cobalt sulphate per ml. had to be added in order to rebalance the tube magnetically. The corresponding change of concentration of the balancing solution is 0·13 mgm./ml., and this is equivalent to a change in its volume susceptibility of $8{\cdot}6 \times 10^{-9}$ c.g.s. units. The change in susceptibility of the contents of the tube is proportional to this value. The proportionality factor, which was determined in separate experiments, is 0·7. Consequently the change in volume susceptibility of the contents of the tube is $6{\cdot}0 \times 10^{-6}$ c.g.s. units and the difference in molar susceptibility between reduced and unreduced vitamin B_{12} becomes $(2{,}300 \pm 200) \times 10^{-6}$ c.g.s. units.

In various experiments values for the difference ranged from $2{,}300 \times 10^{-6}$ to $6{,}800 \times 10^{-6}$ c.g.s. units. These values reflect the extent of the reduction, as well as the degree of decomposition of the reduction product. Solutions which could be considered as completely reduced because of the colour change and the time of reduction showed the greatest increase in susceptibility. Solutions which were still brown in colour (the colour of the intermediate stage) showed changes in susceptibility of only $200\text{–}1{,}000 \times 10^{-6}$ c.g.s. units. After standing, the susceptibility always decreases.

By adding the susceptibility of vitamin B_{12} $(-750 \times 10^{-6}$ c.g.s. units) to the values given above, one obtains the molar susceptibility of the reduced form of vitamin B_{12}. The largest value obtained is about $6{,}000 \times 10^{-6}$ c.g.s. units, which corresponds to about 4 Bohr magnetons. (In calculating this value we neglect the contribution of the organic part of the vitamin B_{12} molecule, which may be 10 per cent of the total susceptibility. This is true as long as free radicals are not formed, which is improbable.) The value of 4 magnetons is at the lower limit for compounds containing bivalent cobalt. This, with what we know of the magnetic properties of monovalent and trivalent cobalt, indicates that the cobalt atom in Schindler's reduction product is bivalent.

We wish to thank Prof. W. Kuhn and Prof. T. Reichstein for their interest in our work, and Prof. Reichstein as well for the gift of several milligrams of vitamin B_{12}, Dr. O. Schindler for his advice in the preparation of the products, and the Cibastiftung of Basle for financial aid for this investigation.

Preparation of Tritium-labelled Dihydrostreptomycin

RADIOACTIVE streptomycin has been prepared by various investigators by biosynthetic incorporation of carbon-14 in the streptomycin molecule. Their aim has been to study actinomycete metabolism. The purpose of the present investigation was to prepare radioactive streptomycin for autoradiographical studies of its distribution in the body.

Streptomycin adds two hydrogen atoms to its molecule by catalytic hydrogenation. The reduction occurs at the aldehyde group and the resultant dihydrostreptomycin is more stable than its precursor[1].

During hydrogenation, it would be advantageous to dissolve streptomycin in a solvent containing no exchangeable hydrogen, otherwise exchange processes would dilute the tritium content of the gas. No such solvent is, so far as I know, reported in the literature, but it was found that streptomycin is soluble in dimethyl sulphoxide. But in this solvent the hydrogenation went on very slowly for five days and stopped when only about 65 per cent streptomycin was hydrogenated. By the addition of a very small volume of water, the reaction was accelerated and stopped after three days when about 85 per cent was hydrogenated.

A microhydrogenation apparatus, with a hydrogenation bottle of only 1 ml. capacity, was constructed. To avoid isotope effects, heavy water was used in the solvent and deuterium gas to complete the reaction.

In the hydrogenation bottle, 100 mgm. streptomycin was dissolved in 0·05 ml. heavy water and 0·30 ml. dimethyl sulphoxide. 4 mgm. platinum oxide catalyst was added. Tritium gas (1 curie) was allowed to react first; then gradually during three days very small volumes of deuterium gas were transferred to the reaction bottle until the hydrogenation stopped.

The product was isolated by filtration and freeze drying. It was then washed with a rather large volume of water to remove exchangeable tritium from the compound. Only tritium atoms bound to carbon are stable.

Analyses for tritium were carried out by combustion of the organic compound and conversion of the tritiated water to tritium. The tritium gas was then counted by introduction into a Geiger–Müller tube[2]. The specific activity was found to be 0·068 mc./mgm. The accuracy in the determination is estimated at ± 20 per cent.

The investigation has been financially supported by a grant from the Knut and Alice Wallenberg Foundation.

Inactivation of the Adrenal Ascorbic Acid-depleting Activity of Pituitary Extracts by Ascorbic Acid

IF extracts of anterior pituitary are incubated for several hours in Ringer's solution containing 1–10 mgm./100 ml. ascorbic acid, their activity on the chromatophores of the isolated skin of *Rana esculenta* disappears[1]. Because of the close chemical relationship between adrenocorticotrophic hormone and intermedin, it seemed of interest to investigate whether the adrenal ascorbic acid-depleting activity of anterior pituitary extracts is also affected by ascorbic acid.

In the following experiments an adrenocorticotrophic hormone preparation of Schering (1 mgm. = 3 I.U.) and ascorbic acid B.P. (Roche) were used; for each group of tests, 0·42 mgm. of the former was dissolved in (*a*) 3·1 ml. pure Ringer (solution *A*), (*b*) 3·1 ml. Ringer containing 8·4 mgm. ascorbic acid per 100 ml. (solution *B*). Both solutions were kept for 18–20 hr. at room temperature. Then, after requisite dilution with Ringer, the adrenal ascorbic acid – depleting activity of solutions *A* and *B* was estimated by the method of Sayers, Sayers and Woodbury[2]. Female rats which had been hypophysectomized 21–27 hr. before the assay were used. In order to exclude errors from the injection of ascorbic acid when assaying solution *B*, the equivalent amount of ascorbic acid was given to all rats receiving solution *A* immediately after the administration of *A*. The results of the experiments show that the activity of solution *B* on the adrenal ascorbic acid concentration was only 1·9 (0·1 – 4·4, $P = 0{\cdot}95$) per cent of the activity of solution *A*. In previous experiments the chromatophore-expanding activity of samples of the same batch of Schering adrenocorticotrophic hormone was found also to be reduced to 4 per cent by the same treatment with ascorbic acid. Ascorbic acid dissolved in Ringer's solution, kept for 18–20 hr. and then injected simultaneously with adrenocorticotrophic hormone, did not seem to interfere with the action of the latter on the concentration of ascorbic acid in the rat's adrenal.

That this inactivating effect of ascorbic acid is not due to a general action of this vitamin on all polypeptides was established by the observation that oxytocin, vasopressin and 'substance *P*' (v. Euler and Gaddum) do not lose their activity when incubated with ascorbic acid.

Details of this work will be published elsewhere.

Propagation of an Air-transmitted Shock Wave in Muscular Tissue

As part of an investigation of the biophysics and physiology of blast injury[1,2], the experiments to be reported here were conducted in order to determine the velocity and damping of a high-explosive shock wave during propagation through a layer of muscular tissue. The velocity of sound in various animal tissues and organs has been extensively studied by Frucht[3]. Concerning the velocity of finite pulses, such as shock waves, no experimental observations are available, and due to the predominance of water in most animal tissues the speed of shock-wave transmission in the body has been supposed to approach that of sound in water[4].

Rectangular pieces of ox thigh muscles (dimensions about 240 mm. × 120 mm. × 60 mm.) were exposed to a high-explosive shock wave in a detonation chamber[1,5]. The time it takes for the wave to cover a known distance was measured by means of two barium titanate crystal pressure-transducers inserted into the meat. The transducer nearest to the explosive charge released the sweep of the recording oscillograph and the distal one recorded the arrival and shape of the wave at the end of the measuring range.

With the low-peak over-pressure used in these experiments (15–30 lb./in.^{2}), the mean velocity of the pressure wave in a covered muscular layer of 170–220 mm. was found to be 650 m./sec., the range being 590–710 m./sec. The relatively great variations are due partly to the inhomogeneous microstructure of the muscular tissue but also to difficulties in determining exactly the arrival of the shock wave at the distal transducer owing to the gradual rise of the pressure curve (see Fig. 1 *B*). The mean velocity during the first 25–50 mm. of propagation was the same as over the whole measuring range, so there was no appreciable slowing down of the wave during the passage of a muscle layer of up to 220 mm.

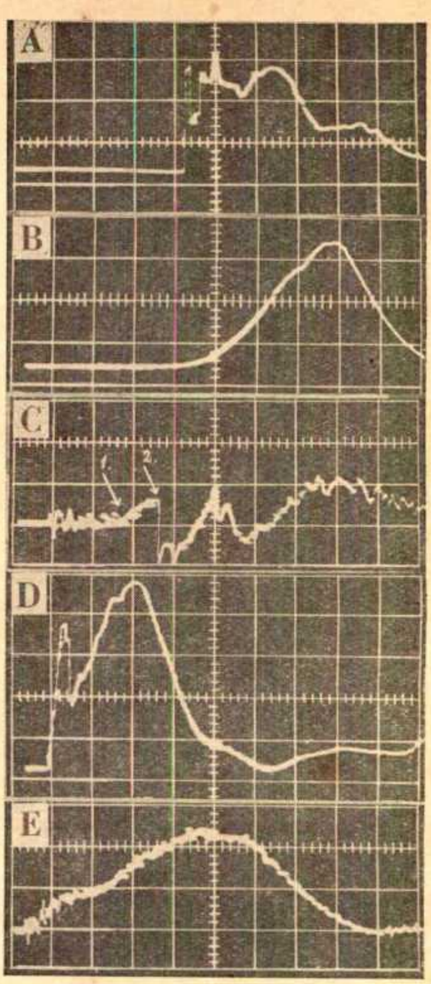

Fig. 1. Recordings of travelling time and pressure curve. Time: 100 μsec. between vertical lines. Pressure: 5 lb./in.^{2} between horizontal lines. The horizontal part of the curves before the increase in pressure corresponds (except in curve *D*) to the passage of the wave through the measuring layer. (*A*) Incident shock wave in air; measuring range, 220 mm.; time of passage, 425 μsec. (*B*) Curve obtained in muscle; measuring range, 200 mm.; time of passage, 330 μsec. (*C*) Differential curve obtained by means of two oppositely coupled transducers, one in the piece of muscle (upward deflexion) and the other in air (downward deflexion), measuring layer with both transducers, 170 mm.; arrows 1 and 2 indicate arrival of wave in muscle and air respectively. (*D*) and (*E*) show steepness of wave-front when the wave has covered a muscle layer of 10 mm. and 25 mm. respectively

The velocity of the incident air shock wave immediately before its impact on the front surface of the meat was 510 ± 10 m./sec. (Fig. 1 *A*).

Due to the inhomogeneity and damping properties of muscular tissue, the steep front of the incident shock wave is already after a very short travel within the meat converted to a wave with a more slowly increasing pressure. In the incident air shock wave, e time interval between the initial increase of ressure is too short to be determined in the recordgs (see Fig. 1 *A*), but it is probably less than 1 µsec. fter having passed a muscle layer of only 10 mm. s in Fig. 1 *D*, the interval is about 40 µsec. and already e passage through 25 mm. of muscle may increase e time to several hundreds of microseconds (in ig. 1 *E* about 420 µsec.). During the further propagaon through thicker muscle layers (see Fig. 1 *B*) the me often becomes shorter and the front of the wave eeper again (cf. Fig. 1 *E* and *B*). With increasing eak pressure in the wave, the time of rise tends to ecome somewhat shorter.

Further investigations are in progress, and a etailed account will be published elsewhere.

Purine Compounds in Snake Venoms

Fischer and Dörfel[1] identified adenosine in the enom of *Bitis arietans* and *Dendraspis viridis* in oncentrations of 12 and 2·6 per cent of the dry veight respectively, and concluded it was a natural omponent of the fresh venom. In the venoms xamined no other nucleoside was found ; nucleotides vere absent but traces of a guanine compound were ot excluded. The present communication reports he identification and estimation of adenosine 3′-phoshate in addition to adenosine in some species of ustralian snake venoms.

The Australian snake venoms were dried *in vacuo* ver calcium sulphate as soon as possible after ollection. These were pooled, powdered and have een stored satisfactorily for immunization studies n stoppered containers over calcium sulphate for eriods of up to twenty years at room temperature. Purine compounds were first indicated in a freezeried preparation of the fraction of the venom of *otechis scutatus* soluble in 50 per cent methanol, btained by the addition of methanol to an aqueous olution of the venom. This fraction in which these ubstances were concentrated, the whole venom, and he products obtained by dialysis, were examined by paper chromatography using a variety of solvents and the photographic technique of Markham and Smith[2]. Adenosine, adenosine 3′-phosphate and a compound of guanine were identified in three of the eight Australian snake venoms examined. Table 1 shows the relative concentrations found in several samples of each of these and two African venoms.

For quantitative analyses, these compounds were removed from the whole venom by dialysis of aqueous solutions of 2–3 mgm. of the venom, in Visking tubing, against two changes of distilled water and agitation overnight at 6° C. The diffused products were freezedried, reconstituted in 0·04 *N* hydrochloric acid and examined in the Beckman spectrophotometer (by courtesy of Dr. R. K. Morton). From the maximum absorption found at 257 mµ, corrected for non-specific absorption, the total concentrations of the purine compounds were calculated in terms of the major component as percentage of the dry weight of the venom, as shown in the last column of Table 1. The differences between the concentrations of adenosine found by Fischer and Dörfel[1] in the venoms of *B. arietans* and *D. viridis*, and those found here in the former venom and the species *D. angusticeps*, may be due in one case to variations between venom preparations and in the other to variations among species of the same genus. The correction for nonspecific absorption applied in the above analyses may account for further variation.

Table 1. CONCENTRATION OF PURINE COMPOUNDS

Species	Adenosine	Adenosine 3′-phosphate	Guanine compound	Per cent weight*
Notechis scutatus	+ ±	trace ,,	trace —	1·4
Denisonia superba	trace ± ±	+ ± ±	— — —	2·0
Acanthophis antarctica	++ + ++	trace — trace	trace — —	2·4
Bitis arietans†	+++	—	trace	3·8
Dendraspis angusticeps†	+++	—	—	4·3

* Molecular extinction of adenosine and adenosine 3′-phosphate = $14{\cdot}6 \times 10^3$ and $14{\cdot}2 \times 10^3$ respectively (ref. 3*a*).
† Gift from the South African Institute for Medical Research.

Paper chromatography of freeze-dried preparations of the 50 per cent methanol-soluble fraction of *N. scutatus* and the products of dialysis of three venoms (Fig. 1) confirms the identification of adenosine and adenosine 3′-phosphate. The component with R_F close to those of adenosine 2′- and adenosine 5′-phosphate was not identical with either of these substances. The 5′-nucleotidase of *Vipera russellii* venom[4] failed to attack it in eluates from the paper. Using butanol solvents in combination with water, ammonia, or acetic acid, this component exhibited

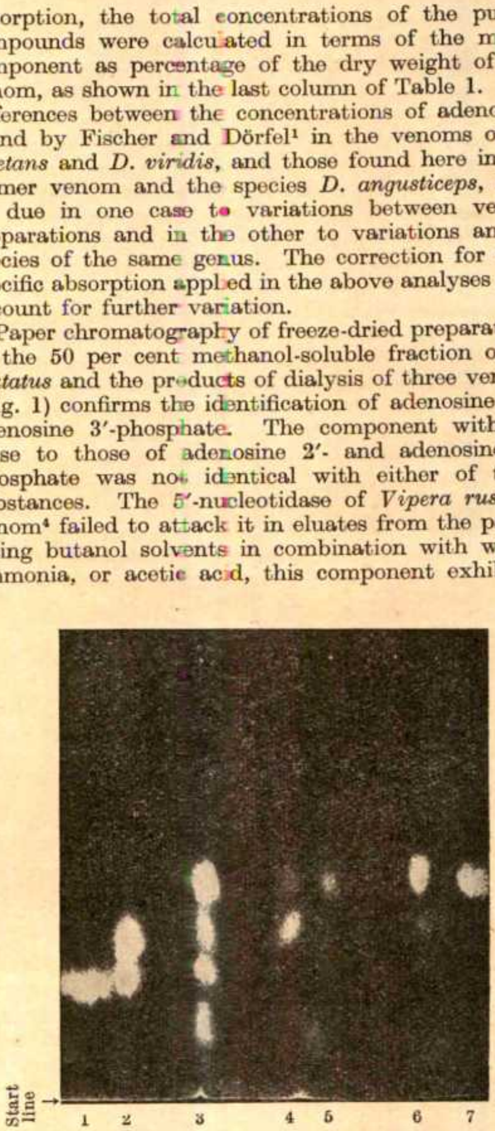

Fig. 1. Photographs of chromatograms. Solvent: sodium dihydrogen phosphate – isoamyl alcohol ; ascending.

(1) Adenosine 5′-phosphate ; (2) adenosine 3′-phosphate and adenosine 2′-phosphate. (3) 500 µgm. 50 per cent methanol-soluble fraction, *N. scutatus*. (4) – (5) 500 µgm. freeze-dried products of dialysis, (4) *D. superba*, (5) *N. scutatus*, (6) *A. antarctica*. (7) Adenosine.

Note, R_F adenosine 2′-phosphate = R_F adenosine 5′-phosphate the fluorescence characteristic of guanine compounds on paper chromatograms[5], and showed an absorption maximum near 249 mμ. The R_F value is consistent with that of guanosine 2′- or 3′-phosphate[3b,6]. The zone nearest the solvent front is attributed to a protein complex absorbing in the ultra-violet region.

The question arises as to whether the adenosine 3′-phosphate and adenosine are natural constituents of fresh venoms or are formed after venom secretion by enzymic action on some precursor. If nucleic acids were their source other bases should have been detected. Of the known coenzymes, only coenzyme *A* could give rise directly to both adenosine 5′- and adenosine 3′-phosphates. However, as the rates of attack by both the 5′-nucleotidase of snake venoms[4] and unspecific phosphatases[7] are considerably faster for the 5′- than the 3′-configuration, one would expect to find adenosine 3′-phosphate in venoms more frequently. In the absence of other evidence it would appear that adenosine, adenosine 3′-phosphate and possibly guanosine 2′-(or 3′-)phosphate are natural constituents of snake venoms (see also Fischer and Dörfel[1]). The direct secretion into milk of enzymes, nucleotides and other metabolic intermediates from the mammary gland is well established[8], while dinucleotides of 2′–5′- and 3′–5′-configuration are now recognized to occur in some tissues[9]. It is therefore suggested that the purine compounds of snake venoms arise directly from the venom glands, which may well yield nucleotides additional to those already identified in the glandular secretions.

I thank the director, Dr. F. G. Morgan, and Dr. J. J. Graydon, of these Laboratories, who made the venoms available, Misses J. Pearson and F. Bates for technical assistance and Mr. K. Rowan for helpful advice. Dr. R. K. Morton made valuable suggestions and collaborated in the preparation of this communication.

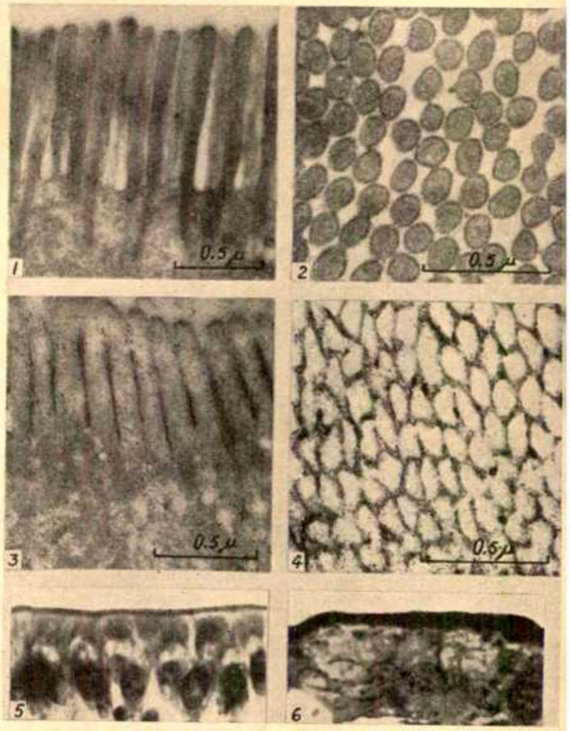
Histochemical Techniques for Electron Microscopy : Alkaline Phosphatase

APPLICATION of histochemical methods to electron microscopy is a logical development of biochemical and biophysical techniques. The comparatively limited resolution of the light microscope fails to reveal the relationship of normal cellular ultrastructure to the sites of histochemical reactions. Therefore, it seemed desirable to utilize recent developments in electron microscopy of biological material[1] in the hope of learning more about the structures demonstrated with these techniques.

An electron microscope study at high resolution (better than 30 A.) of the intestinal epithelium of the mouse has demonstrated that the brush border is composed of minute parallel cylindrical projections of the cytoplasm about 1 micron long and 0·1 micr wide. These projections are bounded by the ce membrane, which appears as two dense lines eac 40 A. thick separated by a non-dense area of 25 The cell membrane is an unbroken unit coveri each projection and continues to adjacent projectio without any discontinuities, either at the apices the base of the projections (unpublished observatio by H. Z.).

High concentrations of the enzyme alkali phosphatase have been demonstrated in the epitheliu of the intestinal mucosa by the method of Gomor and Takamatsu[3], where the reaction is demonstrab principally in the brush border zone[4], and also the Golgi region[5].

The histochemical demonstration of alkaline pho phatase is based on the principle that if enzym containing tissue is incubated with glycerophospha at approximately *p*H 9 in the presence of calciu ions, the phosphate ions liberated will be precipitate at the site of formation as insoluble calcium pho phate. These sites may then be demonstrated by t method of von Kóssa ; in this method the precipitate calcium phosphate is transformed into silver pho



(1) Electron micrograph of mouse intestinal epithelium fixed 2 hr. in 1 per cent isotonic osmium tetroxide solution. Longitudinal section of brush border. × 24.000.

(2) Electron micrograph of mouse intestinal epithelium fixed 2 hr. in 1 per cent isotonic osmium tetroxide solution. Cross-section of brush border. × 35.000.

(3) Electron micrograph of mouse intestinal epithelium fixed 8 min. in 1 per cent isotonic osmium tetroxide solution, incubated 120 min. in Gomori's alkaline phosphatase substrate. Longitudinal section of brush border; positive reaction indicated by dense granular precipitate. × 28.000.

(4) Electron micrograph of mouse intestinal epithelium fixed 8 min. in 1 per cent isotonic osmium tetroxide solution, incubated 30 min. in Gomori's alkaline phosphatase substrate. Cross-section of brush border; positive reaction indicated by dense granular precipitate. × 35.000.

(5) Light micrograph of mouse intestinal epithelium fixed 2 hr. in 1 per cent isotonic osmium tetroxide solution. × 1.000.

ate, which is readily visible in electron micrographs a dense granular precipitate.

For these experiments, in order to avoid the hibition of the enzyme by the osmium tetroxide ative routinely used for electron microscopical eparations, tissues were fixed briefly (8 min. or s) in 1 per cent buffered isotonic osmium tetroxide, ashed in Tyrode's solution and incubated in Gomori's kaline phosphatase mixture for 30 and 120 min. at ° C. The precipitate of calcium phosphate was monstrated by immersion in 0·5 per cent silver trate for ten minutes, after which the tissue was ashed several times in distilled water. This was llowed by graded alcohol dehydration and em- dding in methacrylate. Controls were run by in- bating tissues in substrate containing 0·02 *M* anide.

Electron micrographs of thin sections from the stochemical preparations showed a dense granular ecipitate of silver phosphate distributed uniformly intercylindrical spaces of the projections of the ush border. In sections through the cylindrical ojections parallel or tangential to the cell surface e granular precipitate was arranged like a honey- mb, the cylindrical projections appearing non- nse and the interspaces dense. Preliminary work es not elucidate the relation of the reaction to the ll surface membrane.

Cyanide-inhibited controls showed a normal struc- re without the granular precipitate, eliminating the ssibilities of a false positive reaction. With the ort periods of incubation employed, the possibility diffusion artefacts was minimized[6].

Further investigations with such techniques should ove useful in determining a more precise locus of stochemical reactions than has been possible with ght microscopy and may yield information about e true loci of enzymes.

We thank Dr. F. S. Sjöstrand for the privilege working in his laboratory.

Complementary Action of Melibiase and Galactozymase on Raffinose Fermentation

On the basis of experimental investigations on the heritance of hydrolytic and fermentative ability in easts, we have been led to the conclusion that an xact knowledge of the genotype of the organism mployed is not only desirable but also necessary if he processes of hydrolysis and fermentation are to e studied in detail. Since the existence of six different enes (M_1, M_2, M_3, M_4, M_5 and M_6) responsible for he hydrolysis and subsequent fermentation of maltose as been demonstrated in yeasts (Winge and Roberts[1], illiland[2], and Winge and Roberts (unpublished ork)), and since these genes are not biochemically identical—for example, M_1 hydrolyses both maltose and sucrose and M_2 hydrolyses maltose alone—it is necessary, through appropriate hybridizations and segregations, to isolate each gene individually in a single cultural type in order to investigate the activity of the enzyme synthesized by that particular gene. Otherwise, the presence of additional hydrolytic genes in the culture under investigation may well lead to a confused interpretation of the experimental results.

At present we have isolated, each in a different cultural type, the following genes responsible for the synthesis of hydrolytic enzymes: six maltose-hydrolysing genes, M_1–M_6 (M_5 was, however, isolated by Gilliland), three raffinose- and sucrose-hydrolysing genes, R_1–R_3, and one melibiose-hydrolysing gene, *Me*. In addition, we have isolated two galactose-fermenting genes, *G* and g_s, which bring about rapid and slow fermentation, respectively.

According to the well-known observation of Kluyver, those yeasts which are capable of fermenting at all will always ferment the monosaccharides glucose, fructose and mannose, but not all fermenting yeasts are able to ferment the monosaccharide galactose.

Barring the occurrence of mutation or of nuclear irregularities during spore formation (Winge and Roberts[3]), a yeast hybrid produced by artificially crossing two cultures differing by one fermenting gene will segregate out two fermenting to two non-fermenting single-spore cultures in each of its four-spored asci.

During an investigation of the R_2-gene, which hydrolyses raffinose in such a way that the fructose portion of the molecule is liberated and afterwards fermented, while the melibiose portion remains intact, we produced a series of R_2r_2-hybrids. All the tetrads of these hybrids were expected to segregate out as $2R_2 : 2r_2$, that is, two single-spore cultures capable of fermenting raffinose and two non-fermenting single-spore cultures. The segregations obtained, however, were most surprising in that we found, of a total of 119 tetrads from five different R_2r_2-hybrids, the following:

$4R:0r$	$3R:1r$	$2R:2r$
4	68	47

This was not a one-gene segregation, nor was it a typical two-gene segregation, in which the frequency of the segregations 4 : 0, 3 : 1, and 2 : 2 should theoretically occur in the ratio 1 : 4 : 1. A two-gene segregation, however, could not be expected to occur since the hybrids contained R_2 alone.

A series of planned genetic experiments finally led to an explanation of these segregations. We were aware that all five hybrids were also heterozygous with respect to both the melibiase and galactozymase genes, so that their genotype could be written as $R_2\ Me\ G/r_2\ me\ g_s$. Our working hypothesis, which proved to be correct, assumed that the complementary action of $Me + G$ results in the fermentation of one-third of the raffinose molecule, the galactose portion being fermented away by galactozymase and the sucrose portion remaining intact. If, however, R_2 is also present, then the raffinose molecule is completely fermented due to the hydrolysis of sucrose into fructose and glycose by β-*h*-fructosidase.

Our segregation results showed that the melibiase gene and the galactozymase gene were weakly linked. Assuming the existence of complementary genes and of approximately 40 per cent crossing over, then the theoretically expected raffinose segregations (1 : 19 : 16) of the 119 asci are as follows:

4 *R* : 0 *r*	3 *R* : 1 *r*	2 *R* : 2 *r*
3·3	62·8	52·9

which, as can be seen, are in satisfactory agreement with the segregations actually obtained.

The final proof of the correctness of this hypothesis of complementary action would naturally consist in the genetic analysis of a hybrid which had been produced by crossing an *Me* g_s genotype with an *me G* genotype, neither of which contained any other hydrolytic or fermentative genes (except, of course, the zymase complex for glucose fermentation). These two parent types would each be unable to ferment raffinose, but the hybrid, *Me* g_s/*me G* should, according to the hypothesis, be able to hydrolyse raffinose and ferment the liberated galactose, resulting in a one-third raffinose fermentation.

Eight hybrids of this genotype (*Me* g_s/*me G*) were produced. Each of them was capable of fermenting raffinose after four to seven days.

Even more interesting were the segregation ratios obtained from the offspring of one of these hybrids. Theoretically, the spore tetrads from an *Me* g_s/*me G* hybrid should yield the following results:

Relative frequency	Type of tetrad	Raffinose fermentation
1	2 *Me G* : 2 *me* g_s	2+ : 2−
1	2 *Me* g_s : 2 *me G*	0+ : 4−
4	1 *Me G* : 1 *Me* g_s : 1 *me G* : 1 *me* g_s	1+ : 3−

Six asci from one *Me* g_s/*me G* hybrid were analysed; of these, five gave a 1 : 3 raffinose segregation and one gave a 2 : 2 raffinose segregation. All the seven raffinose-fermenting single-spore cultures fermented both melibiose and galactose (the latter rapidly), while none of the remaining seventeen single-spore cultures was able to ferment both sugars.

On the basis of these results, we propose the following scheme for the gene action responsible for the hydrolysis and fermentation of the raffinose molecule (Fig. 1).

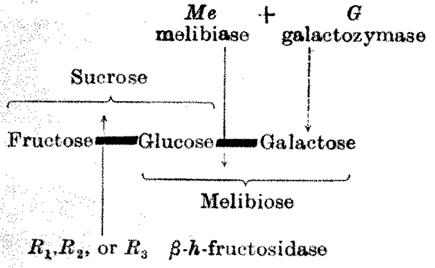

Fig. 1. Gene action involved in the hydrolysis and fermentation of the raffinose molecule

It can be seen that raffinose may be hydrolysed through the activity of R_1, R_2, or R_3 into melibiose and fructose, the latter being fermented by the zymase complex present in all fermenting yeast cells. On the other hand, raffinose may also be hydrolysed through the activity of the *Me*-gene into sucrose and galactose, the latter being fermented by galactozymase. Mr. Manuel Losada, of Madrid, has assisted us by demonstrating that the *Me*-gene in the absence of the *G*-gene is capable of hydrolysing raffinose, in that after growth of an *Me r* yeast type in a raffinose medium the substrate reduces Fehling's solution, thus showing the presence of galactose. As a control, an *me r* yeast type was grown in the same medium; here Fehling's solution was not reduced.

It is for this reason that we speak of complementary gene action with respect to raffinos fermentation rather than raffinose hydrolysis. Th latter process is carried out by the *Me*-gene alone but in order to ferment the raffinose molecule b complementary gene action, *G* must be presen together with *Me*.

Finally, it should be mentioned that the gene g_s which requires long-term adaptation in order t bring about the fermentation of galactose (Wing and Roberts[4]), is also responsible for the slow fermentation of raffinose in co-operation with *Me*. I has also been established that the fermentation c raffinose through the action of the *R*-genes (to th left in Fig. 1) takes place more rapidly than th fermentation of raffinose through complementar action, presumably because fructose may be fermented more rapidly than galactose.

A detailed account of these investigations wi appear in the *Comptes Rendus des Travaux d Laboratoire Carlsberg*.

Chromosome Number in Rabbit Blastocysts

DURING recent years a series of papers have appeared discussing the constancy or inconstancy in the chromosome number in mammalian tissues. It is now generally agreed that some tissues show a certain degree of inconstancy in the chromosome number either by having aneuploid cells[1] or by developing more constant euploid (or polyploid cells[2]. I have shown[3] that by careful attention to technique, including pre-treatment in hypotonic saline solution and using a gentle squash, about 95 per cent of the cells in rabbit blastocysts (five days old) will appear normal with $2n = 44$, whereas 2–3 per cent have hypo- or hyper-ploid numbers. The reason for low numbers seems in many cases to have been mechanical disturbances introduced by the squash technique.

In a review of the chromosome number in mammalian somatic cells, Beatty[4] raises the question, how early in life the inconstancy originates. Beatty (in collaboration with M. Fischberg) found from haploid to tetraploid cells and few hexaploid cells in mouse blastocysts as early as 3½ days after fertilization. We have examined rabbit blastocysts of five days of age and found the results already mentioned. However, it is of interest to try to find whether the heteroploid cells appear only in certain tissues or if they can arise anywhere in the young embryos. By the way, attention is directed to the fact that in most cases the inconstancy in chromosome numbers has been found in dying tissues and in transitory embryonic membranes (cf. refs. 4, 5). In the following, results are presented of an attempt to count the chromosomes in two different parts of the rabbit blastocyst, described simply as the trophoblast and the embryonic disk.

Due to the small size of the five-day blastocyst, specimens six days old were used in this case. The blastocysts were washed out from the uterine horns and immediately placed in an incubator at 37° C. in a 0·45 per cent saline solution, according to the routine method now used in our laboratory[6]. After pre-treatment, the specimens were fixed in alcohol – acetic acid for 1 hr. and stained according to the Feulgen method for at least 20 min. After staining, a single blastocyst was placed in glycerine in a hollow-ground slide (hanging drop slide), and by use of a micromanipulator the embryonic disk was separated from the trophoblast layer. The two parts were then squashed on separate slides, applying only very gentle pressure. The trophoblasts were more difficult to handle than the embryonic disks.

Twenty-six blastocysts were used, and 104 metaphase plates could be counted from embryonic disks, of which 101 plates had $2n = 44$, one had 41 chromosomes while two plates had clearly 66 chromosomes. From the trophoblast cells, 46 plates were counted. One cell had only 33 chromosomes, four cells had 41 chromosomes each and 41 cells had $2n = 44$ chromosomes. Although a χ^2-analysis shows a small difference ($P < 0·05$) in the distribution of the number of cells with deviation in chromosome numbers between trophoblast and embryonic disk cells, this is not regarded as of significant importance, and it is concluded that aneuploid or polyploid cells appear with the same frequency in the two parts of the blastocyst examined up to the age of six days. It should be mentioned that the total number of abnormal cells—although few—is of the same magnitude, namely, 5 per cent, as found in the earlier work[3].

I am indebted to Mr. Per-Jonas Åström for his valuable help throughout this work.

Selection for Heterozygotes during Inbreeding

RYE is normally an outbreeding species. When the plants are forced to inbreed by self-pollination, the progeny, being more homozygous, are, as is usual in such species, less vigorous and less fertile than the heterozygotes which comprise a normal population. Since heterozygotes are superior in this way to the homozygotes, it could be expected that, during the course of inbreeding, natural selection would favour to some extent the more heterozygous genotypes. To test this assumption, we have made use of chromosome structural changes where genotypes heterozygous and homozygous for the chromosome segments involved are easily distinguished.

In 1950 an F_1 plant from a cross between two inbred lines was found to be heterozygous for two separate and distinguishable interchanges, *A* and *B*. This F_1 plant was self-pollinated. From the F_2 generation three of the plants which were heterozygous for both the interchanges were selfed and the inbreeding was continued in subsequent generations by selfing a double heterozygote in each of the three families. As a result of inbreeding depression, the proportion of the seeds sown which reached maturity was generally low from F_2 onward and in no family was it higher than 77 per cent. Samples of the mature plants were scored at meiosis. In the absence of selection, the progeny from selfing a plant heterozygous for two separate interchanges would be expected to consist of four equal classes in respect of structural homozygosity and heterozygosity, namely, Hom. *A* Hom. *B*, Hom. *A* Het. *B*, Het. *A* Hom. *B*, Het. *A* Het. *B*. Selection for or against one or both heterozygotes will upset this ratio. The distributions observed in the four inbred generations are given in Table 1.

Table 1. DISTRIBUTIONS OF HOMOZYGOTES AND HETEROZYGOTES IN RESPECT OF TWO INTERCHANGES, *A* AND *B*. EACH FAMILY IS DERIVED FROM SELFING A DOUBLE HETEROZYGOTE

	Family	Hom. *A* Hom. *B*	Hom. *A* Het. *B*	Het. *A* Hom. *B*	Het. *A* Het. *B*
F_2		5	9	11	7
F_3	1	1	1	2	4
	2	5	5	8	4
	3	5	3	6	5
F_4	1	3	4	9	13
	2	8	6	10	10
	3	0	1	7	7
F_5	1	2	5	4	2
	2	2	1	3	5
	3	2	0	1	5
	Total	33	35	61	62

Contingency χ^2 analyses of these results show (1) no significant heterogeneity between generations or families, and (2) the interchanges to be distributed independently of one another. The results from all generations may therefore be pooled and the interchanges analysed separately. The distributions in respect of *A* and *B* in the total progeny are:

	Hom.	Het.	Total
Interchange *A*	68	123	191
Interchange *B*	94	97	191

The distributions of *A* and *B* are significantly different ($\chi^2_{[1]} = 7·246$, $P = 0·01–0·001$). The proportion of homozygous to heterozygous *B*'s is not significantly different from the 1 : 1 ratio expected when neither class is at a selective advantage. In the case of *A*, however, there is a significant excess of heterozygotes. We conclude from this that the genotypes heterozygous for interchange *A* enjoy a selective advantage over the homozygotes. It is to be noted that the selection operates in favour not of heterozygotes in general but of a particular heterozygous combination, which indicates that heterozygosity in itself is not necessarily advantageous. These conclusions agree with Darlington and La Cour's findings[1] in *Campanula*, a species in which interchanges are commonly found in wild populations. A selective advantage of structural (inversion) heterozygotes is, of course, well known from the work of Dobzhansky[2] and his collaborators, and others[3], in *Drosophila*. White[4] also has concluded that certain chromosome structural heterozygotes are at an advantage in populations of grasshoppers.

An excess of heterozygotes could possibly be interpreted in terms of a major gene showing some degree of lethality in a homozygous state. A phenotype with yellowish leaves in the seedling stage which appeared during the course of this experiment was probably determined by a recessive gene of major effect. All those examined were found to be homozygous for interchange *A*, from which we conclude that the gene is located on one of the chromosomes involved in this interchange. It is clear, however, that this major gene difference does not account for the excess of heterozygous *A*'s, because the homozygous *A* plants which are 'yellow' survive as well as those which are green. The ratio of the two types was in fact 16 'yellow' to 11 green. Although we cannot entirely rule out the possibility of some major gene affecting the results, an alternative, and more likely, explanation is that the advantage of the *A* interchange heterozygotes is due to a superior balance of polygenes in heterozygous combinations. We can therefore make use of these interchanges for genetic investigations of rye populations in much the same way as inversions have been used by Dobzhansky in *Drosophila*.

Chromosomal Polymorphism in a Bark Weevil

The North American bark weevil, *Pissodes approximatus* Hopk., has three different chromosome numbers, namely, 30, 31 and 32, due to what White[1] has called 'centric fusion' of non-homologous autosomes. The 'fusion' homozygote consequently has two large V-shaped chromosomes instead of four smaller rod-shaped chromosomes, and the 'fusion' heterozygote has one V and two rods that form a trivalent in primary spermatocytes (Fig. 1).

Although chromosomal polymorphism of this type is well known in the Orthoptera[2], mainly no doubt because the order has received considerable attention from insect cytologists, this constitutes the first recorded example of the phenomenon among the five hundred or so beetles that have been examined to date. It is nevertheless quite certain that almost 10 per cent of the species have evolved neo-*XY* sex chromosomes through 'centric fusion' of the *X*-chromosome with an autosome, their mode of origin being revealed in the heterogametic male by the morphology and differential staining of the sex-determining complex. However, that the process, as confined to autosomes, must have contributed in large measure to the multiplicity of chromosome numbers found in the Coleoptera[3] is attested by the number of cognate species and neighbouring genera in which the one with the lower chromosome number has a relatively large pair of autosomes. Nevertheless, until this direct demonstration, their true mode of origin has been a matter of inference.

So far, a total of sixty-seven adults, mostly males, have been examined from widely scattered areas in Ontario. At least two of the three types occur in each area, but none has been studied intensively enough to test for deviation from the Hardy–Weinberg equilibrium. However, since the species apparently breeds at random in well-defined populations, an investigation of their genetical dynamics may be expected to reveal much of the mode of operation of natural selection under different environmental conditions and elucidate the problem of the genetical evolution of populations and geographical races of insects.

Nucleus and Spindle of *Bacillus megatherium* in Fission and Sporulation

The cells of *Bacillus megatherium* have been stained by DeLamater[1], Fitz-James[2], Robinow[3] and others with various dyes to show the chromatin-threads after pretreatment with perchloric acid, chloric acid or other reagents. Chromosomes have been observed occasionally in mitosis as well as a structure which I identify with the spindle described by Lindegren *et al.*[4] in the yeast cell. The large ellipsoidal nucleus containing the chromosomes in the centre of the bacterial cell can be observed in the living cell. This structure is identical with that which DeLamater[1] observed in stained material of *Bacillus megatherium* and which Whitefield and Murray[5] observed in stained cells of *Shigella dysentriae*. The chromosomes appear when dried (unheated) bacterial smears are stained with 1 per cent aqueous gentian violet. They are not clear when stained directly with Giemsa solution but stain clearly with Giemsa after pretreatment with 10 per cent perchloric acid for 20 min. (Fig. 1,*a*).

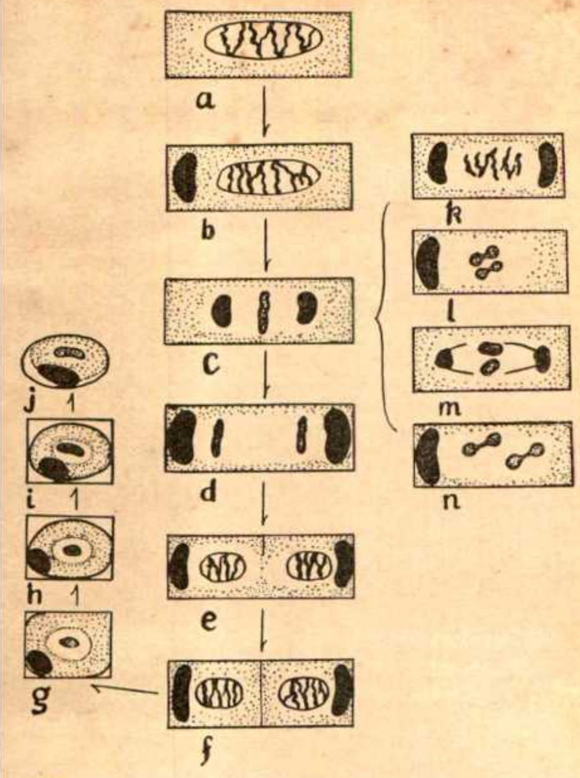

Fig. 1. Schematic representation of *Bacillus megatherium*. (*a*) Resting nucleus, (*b*) prophase, (*c*) metaphase, (*d*) anaphase, (*e*, *f*) telophase, (*g*–*j*) spore formation, (*k*–*n*) various figures of metaphase

The chromosomes are Feulgen-positive (1) after fixation with 75 per cent alcohol, or (2) Carnoy's fluid, or (3) after pretreatment with 10 per cent perchloric acid for 20 min., or (4) without fixation.

A large body on one side of the nucleus stains directly (1) with iron aceto-carmine solution, (2) with 1 per cent aqueous gentian violet, (3) with Giemsa, or (4) with 0·1 per cent aqueous vital red—but it is Feulgen-negative. It seems to appear when the cell enters prophase. After pretreatment with 10 per cent perchloric acid it is stained by either gentian violet or Giemsa. It corresponds to the spindle of the yeast cell[4], although its staining reaction is somewhat different. It is inferred to be the spindle from consideration of its behaviour in mitosis. It corresponds to what Robinow and Murray[6] named "the deeply stained cytoplasm" in *Bacillus cereus*. I identify this structure as the spindle-body.

Small granules often appear in the cell after staining with 1 per cent aqueous Janus green which are thought to be chondriosomes.

When the mitosis begins a single spindle-body appears at one end of the cell (Fig. 1,*b*), and as mitosis proceeds (Fig. 1,*c*–*e*,*k*,*m*) two spindle-bodies appear, one on each side of the nucleus. Between the two spindle-bodies the chromosomes change into one or two blocks of unresolvable chromatin (Fig. 1,*c*,*l*,*m*,*n*). At telophase a separation-wall is formed; each daughter cell contains one nucleus and one spindle-body (Fig. 1,*e*,*f*).

Preceding spore formation the cell divides transversely into a chain of smaller cells. The protoplasm of each small cell becomes ellipsoidal with the nucleus in the centre (Fig. 1,*g*,*h*). The large body in the cytoplasm beside the nucleus (Fig. 1,*g*,*h*) was called the 'peripheral body' by Fitz-James[2] and the 'side-body' (in the *Bacillus cereus*) by Fitz-James, Robinow and Bergold[7]. Each ripe spore contains a large 'side-body' and a nucleus in the centre of the cytoplast (Fig. 1,*i*,*j*). The 'side-body' corresponds to the 'eccentric nucleus' observed by Robinow[3].

The nuclear vacuole with its enclosed chromatin was called the 'basophilic ring' by Fitz-James[2] and the 'basophilic central core' by Fitz-James, Robinow and Bergold[7].

Only the spore coat of the spore stains with 1 per cent aqueous gentian violet or Giemsa, but after pretreatment with 10 per cent perchloric acid, both the nucleus and the 'side-body' are stained. Usually after pretreatment with 10 per cent perchloric acid only the chromosomes are Feulgen-positive, but occasionally the 'side-body' is Feulgen-positive because deoxyribonucleic acid of the nucleus has been retracted on to the 'side-body' (spindle).

In spores fixed with 45 per cent acetic acid or Carnoy's fluid and then stained with 1 per cent aqueous gentian violet (after pretreatment with 10 per cent perchloric acid for 20 min.) the 'side-body' and the chromosomes stain deeply, indicating that the 'side-body' and the nucleus are independent structures and that the 'side-body' is identical with the spindle-body.

I wish to express my cordial thanks for providing facilities for the present study and for criticism of the manuscript to Prof. Carl C. Lindegren, chairman of the Department of Microbiology, Southern Illinois University.

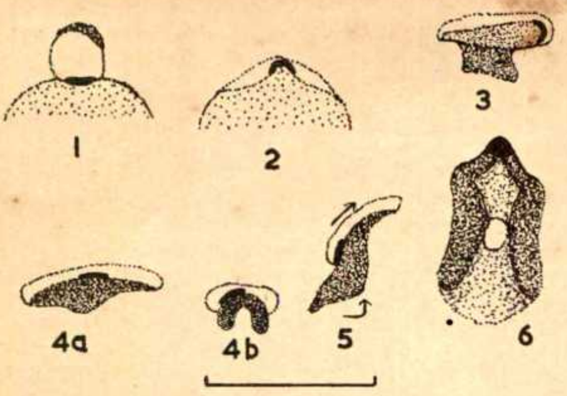
Acrosome Formation in Bandicoot Spermiogenesis

THERE has been some disagreement about the presence of an acrosome in marsupial spermatozoa. Students of spermiogenesis[1] are generally agreed that none is present, whereas Retzius[2] found a diminutive body at the proximal end of the mature sperm head in some species, although not in *Didelphys*[3]. As Bowen[4] remarked, such apparent exceptions to the universal presence of an acrosome in animal sperm are important. A study of spermiogenesis in the bandicoot (*Perameles nasuta*), previously reported to lack an acrosome by Benda[1], has shown that an acrosome is indeed present, although its method of formation presents some unique features. For study of the process, specific staining[5] by the periodic acid – Schiff procedure[6] was essential. The staining was preceded by digestion with saliva and followed by staining with toluidine blue. With classical methods it was impossible to be certain of the presence of an acrosome at any stage.



Figs. 1–6. Camera lucida drawings of the acrosome of the bandicoot at various stages of development. The granular component is solid black, the archoplasmic vacuole is unshaded, while the nucleus, except for the nuclear aperture in Fig. 6, is stippled. Figs. 4*a* and 4*b* are lateral and polar views, respectively, of cells at the same stage of development. The upper margin in all figures, except 1, is directed towards the Sertoli cell. The scale beneath the figures represents 10μ (Figs. 1–5) or 6·8μ (Fig. 6)

As in other animals[4,7], a vacuole is formed in the archoplasm relatively early in spermatic development and within this vacuole a small granule is laid down. Almost immediately, this granule becomes applied to, and flattened against, the nuclear membrane (Fig. 1). No further growth of the flattened granule, later to become the granular component of the acrosome, occurs. An outgrowth from the nucleus diminishes, and finally appears to close, the vacuole (Fig. 2).

Owing to the peculiar process of nuclear condensation, the granular component is carried to a point at one side of the now flattening nucleus (Fig. 3). This point marks the future proximal end of the sperm head. During the nuclear condensation the vacuole again becomes evident; with further condensation and flattening of the nucleus, it becomes considerably lengthened and increased in volume. At the same time the granular component becomes dislocated from its previous position and is now found at a variable position on the dorsal surface of the much flattened and now partially folded nucleus (Fig. 4 *a*,*b*).

After rotation of the nucleus through 90°, a process which brings its long axis radial with respect to the seminiferous tubule and in line with the axial filament, the vacuole becomes reduced in volume and moves towards the proximal end of the nucleus. During this shrinkage of the vacuole the granular component is carried along the dorsal surface and towards the proximal end of the nucleus, by now almost transformed into the mature sperm head (Fig. 5). The granular component finally comes to rest at the tip of the rostrum of the mature sperm head (Fig. 6). Here it forms a conical cap of diameter 1·4μ, height 0·6μ and thickness 0·3μ. The shrinking vacuole becomes attached to the base of the conical rostrum of the sperm head, finally forming what corresponds to a dorsal head cap, although not normally visible as such. Thus both the granular and vesicular derivatives of the archoplasm contribute to the formation of the acrosome in the mature sperm.

Acrosome formation in the bandicoot is unusual in a number of respects: (1) the absence of growth of the granular component, which is normally merely a proacrosome; (2) the earlier hypertrophy, very late condensation, and changing insertion of the archoplasmic vacuole; (3) the dislocation of the granular component of the acrosome from its original position. The latter is quite different from the complex migrations undergone by the proacrosome in some Hemiptera[8].

Components of the Total Magnesium Content within the Leaves of White Clover and Perennial Ryegrass

LITTLE information exists concerning the quantitative relationships between the forms in which magnesium exists within leaves. Chlorophyll concentrations in leaves have frequently been measured[1], but rarely has this been done simultaneously with estimations of the total magnesium content.

Fully green leaves of perennial ryegrass (*Lolium perenne*) and *S*100 white clover (*Trifolium repens*) were gathered from plants growing in the field on Sept. 20, the petioles of the clover leaves were removed, and approximately 2 gm. of fresh material was extracted in 80 per cent acetone. The residual colourless material was designated 'fibre'; the ryegrass residue looked like cotton wool, that from the clover was more powdery and less fibrous.

The chlorophyll concentration in the solution was determined on a Unicam *S.P.*500 spectrophotometer by the method of MacKinney[2], whose values for the molecular extinction coefficient of chlorophyll *a* and chlorophyll *b*, in acetone at 6630 A. and 6450 A., were confirmed by Holt and Jacobs[3]. In this determination the assumption was made that no compounds in the solution other than chlorophyll *a* and chlorophyll *b* were absorbing light at 6630 A. and 6450 A. The total magnesium concentrations in the fibrous fraction and in the original material were determined, after ashing at 550° C., by the method of Mason[4].

The 'chlorophyll magnesium' was calculated from a knowledge of the formulæ of chlorophyll *a* and chlorophyll *b*, and the values obtained for the ratio chlorophyll *a*/chlorophyll *b*. The magnesium which could neither be attributed to the chlorophyll molecule nor existed within the fibre fraction was designated 'residual magnesium' and was probably mostly soluble in water.

In Table 1 results are given comparing the composition of the leaves of ryegrass and clover. In Table 2 are values of the proportions of the various forms of magnesium (as percentages of the total magnesium content) within these same two types of leaf. All values are the mean of three replicates.

Table 1. Composition of Leaves of Clover and Ryegrass

	% Dry matter (fresh wt. basis)	%Chlorophyll (fresh wt. basis)	%Chlorophyll (dry wt. (basis)	% Fibre (dry wt. basis)	% Mg in leaf (dry wt basis)	% Mg in fibre (dry wt. basis)	Chlor. *b* / Chlor *a*
White clover	19 4±0 06	0 219±0 001	1·13±0 02	65·52±1 08	0 2365±0 000[illegible]	0·1478±0 0019	1 : 2·88±0 052
Perennial ryegrass	16 9±0 22	0 199±0 002	1·18±0 02	70·63±0·26	0 1803±0·0035	0·0960±0·0056	1 : 3 07±0 039

Table 2. Distribution of Leaf Magnesium as Percentage of Total Magnesium Present

	In fibre	In chlorophyll	Residual magnesium (by subtraction)
White clover	62 47±0 64	12·86±0 03	24 67±1 00
Perennial ryegrass	53 29±2 71	17 75±0 61	28·96±2·94

These results indicate that both the maximum concentration of chlorophyll (0·20 per cent fresh weight basis) and the ratio of chlorophyll *a* to chlorophyll *b* (2·5 : 1) given by Hill and Whittingham for green leaves[1] may be exceeded in ryegrass and clover.

Also the fact that more than 50 per cent of the magnesium in these two types of leaf is located within the 'fibre' fraction may affect the availability of this element to animals feeding on these two pasture plants. This in turn may be of significance in the study of the incidence of hypomagnesæmia[5] in the grazing animal.

Nasal Trichobilharziasis : a New Avian Schistosomiasis

In the course of research on the schistosomes of birds in the Belgian Congo and in the Ruanda-Urundi, I have discovered schistosomes in the nasal cavities of birds[1]. Nasal schistosomiasis is known to affect cattle in India, but it does not seem to have been mentioned in birds.

All parasites that were discovered—there being five new species—belong to the genus *Trichobilharzia* Skr. and Zakh. (1920). Nasal schistosomiasis is very common in the Anatidae. At Astrida (Ruanda-Urundi) we have observed it in the yellow-bill duck (*Anas undulata undulata*), in the spurwing goose (*Plectropterus gambensis*), in the Egyptian goose (*Alopochen aegyptiacus*), in the white-faced duck (*Dendrocygna viduata*) and in the knob-billed duck (*Sarkidiornis melanota*). Further, we have also met it in the Hadeda ibis (*Hagedashia hagedash* Ciconiiformes) and in the grebes (*Podiceps* and *Poliocephalus*).

The adult schistosomes are found in the small veins of the nasal cavities, and the eggs, often in great numbers, are met with in the nasal mucus. It is remarkable that the *Trichobilharzia* of the nasal cavities are exclusively found in these organs, and never in the liver or in the intestinal veins.

The histopathological lesions consist in a thickening of the nasal lining together with an accumulation—often considerable—of lymphocytes and the presence of numerous and voluminous giant cells. Sometimes additional infection is noted together with necrosis.

The discovery of this schistosomiasis opens a new field of research to the parasitologist, and promises to be fruitful. It is also of considerable interest from the medical point of view. Indeed, we know that the cercaria of *Trichobilharzia* are capable of causing a dermatitis known as 'swimmer's itch'. Recently, B. de Meillon and N. Stoffberg[2] have reported the first case in Africa of 'swimmer's itch', and I described, at Astrida (Ruanda-Urundi), a new furcocercaria of the Ocellata group which produces experimentally the same skin affection[3].

Up to now, no attention has been paid to the role that cercaria could take in the pathogeny of pruriginous skin diseases in Central Africa. I am reporting my observations in order to direct attention to this highly important matter.

Sulphate Deficiency of Lake Victoria

An article by Beauchamp[1] suggests that a sulphur shortage in Lake Victoria is a factor limiting the growth-rate of fish. Owing to the fact that sulphates are removed from the water by biological precipitation in the form of plant and animal remains, Beauchamp suggests that the sulphate ultimately becomes anaerobically reduced to insoluble and unavailable sulphides which accumulate in the mud of the lake bed. Thus, although the water is deficient in sulphur, the element may well be present in large quantities at the bottom of the lake. In order to obtain facts as to the distribution of sulphur in the water, mud and vegetation of Lake Victoria, a preliminary investigation has been undertaken in the small northern area around Jinja.

So far as the area examined is concerned, the results have confirmed Beauchamp's statement that the water of the lake is deficient in sulphur. The sulphate concentration was less than one part per million at all depths, and the total sulphur content was mainly one to two parts per million. The analyses of the muds have revealed several interesting facts. Sulphur was present in abundance (3,000–20,000 p.p.m. dry mud), not as expected in the reduced form of sulphide but practically wholly in the organic form. Only about 1–4 per cent of the total sulphur was present as sulphide and 2–8 per cent as sulphate. Iron was present in both the reduced and oxidized forms in approximately equal proportions, and the oxidation-reduction potentials indicated a condition more on the oxidizing side than the reducing. These results seem to indicate that anaerobic conditions do not exist to any great degree at the lake bottom. Koyama *et al.*[2] found a similar lack of reduced sulphur in certain lakes in Japan, and they attributed this to low iron contents associated with high manganese contents. The mud of Lake Victoria, although containing appreciable amounts of manganese, is relatively rich in iron and thus the same explanation may not apply.

The next point arising from the analyses is that although the mud-surface contained considerable amounts of sulphate, the water immediately above it was devoid of the ion. For example, one mud-surface contained 700 p.p.m. sulphate-sulphur by Morgan's reagent, yet the water filtered from it had less than 1 p.p.m. A similar condition has been found by Koyama *et al.* in Japan. These workers suggested that a colloidal ferric complex selectively sorbs sulphate ions from the water. Mortimer[3] found colloidal ferric complexes in English lake muds that adsorbed sulphates and other ions. On reduction, these complexes were destroyed and liberated the adsorbed ions; this was controlled by the balance between the reducing power of the mud and the amount of oxygen supplied to its surface. As the results for Lake Victoria have shown the muds to be in an oxidized rather than a reduced state, it can be expected that similar adsorbing processes would occur. This conclusion suggests that the observed shortage of soluble sulphates in the water is due, not to their reduction to sulphides, but to the oxidized state of the mud-surfaces.

Sulphates are removed from the water biologically in the formation of plankton and other vegetable matter, and thus sulphur is also incorporated into the mud in the organic form. Beauchamp has stated that the limiting factor in lake fertility is the rate of decomposition of such precipitated organic matter. However, as the reduction of the mud-surface could increase the supply of soluble nutrients, the oxidation-reduction potential of the mud is also an important factor affecting fertility.

Crystal Structure of Tobermorite

We have examined the crystal structure of tobermorite, using crystals given to us by Mr. J. D. C. McConnell, who has published a preliminary description of them[1]. The substance is a hydrated calcium silicate, closely related to, or identical with, the calcium silicate hydrate I found by Taylor[2] in set cements. Its composition, as found by McConnell[1], is $Ca_6Si_6O_{22}H_{10}$, and this is compatible with our present results, so far as they go.

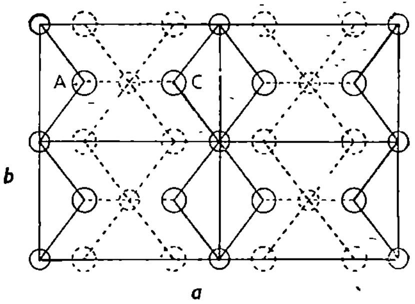

Fig 1(*a*)

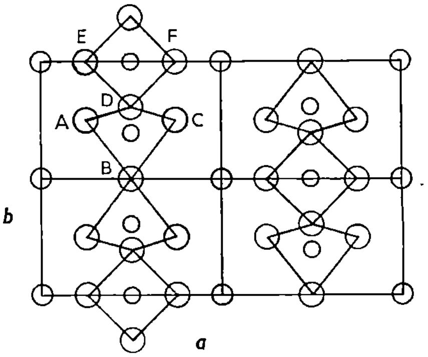

Fig 1(*b*)

Fig. 1. Small circles Si, intermediate circles Ca large circles O. Atoms and bonds shown dotted lie below middle of layer (*a*) Tobermorite: two central sheets of layer projected on (001)—idealized. (*b*) Tobermorite: upper half of layer projected on (001)—idealized

The crystals, a few tenths of a millimetre long, were studied by Weissenberg and oscillation photographs. They turned out to be composite, giving doubled spots, and also giving diffuse scattering of a kind which indicates structural 'mistakes', rather similar to, but not identical with, those found in β-wollastonite[3]. In spite of these effects (which are being studied, but will not be described in detail here) it proved possible to determine the structure in general outline.

The crystal structure is very nearly orthorhombic. It can be described on orthogonal axes with $a = 11 \cdot 3$ A., $b = 7 \cdot 33$ A., $c = 22 \cdot 6$ A.; cell-contents, four formula-units. There are systematic absences of hkl for $h + k$ odd and $\frac{1}{2}(h + k) + l$ odd, indicating that the true unit cell is smaller and implying a symmetry which cannot be greater than monoclinic, with c as the possible symmetry direction. There are systematic weaknesses of hkl for h odd or k odd, indicating a close similarity between the four quarters of the pseudo-orthorhombic cell. (It is convenient to continue to use this cell, and the axes defined by it.)

The cell contains two identical complex layers parallel to (001), displaced relative to one another in projection on (001), and each having a centre of symmetry (at least to the present degree of approximation). Each layer has two central sheets, of composition $4CaO_2$, arranged so that each calcium has four oxygen neighbours in its own sheet and two in the sheet at the next level (see Fig. 1*a*). Each pair of adjacent oxygens, such as *AC*, forms one edge of a tetrahedron containing silicon. These tetrahedra are joined into chains running parallel to *b*, as shown in Fig. 1*b*. Both Figs. 1*a* and 1*b* are slightly idealized; the actual chains are somewhat puckered.

This arrangement, a complex layer with the composition $4(Ca_2Si_3O_9)$, forms the backbone of the tobermorite structure. It is rather like a piece of double-sided corrugated paper, having a strong central sheet reinforced on each surface by longitudinal ridges; but the ridges are themselves toothed, since *E*, *F* (Fig. 1*b*) are at a considerably higher level than *B*. Two sheets pack together with their ridges superimposed vertically. There are grooves between the ridges, and these or the interlayer spaces must hold the remaining calcium and oxygen atoms, but their detailed positions are not yet known. Neither is it known whether the hydrogen atoms are present wholly in OH groups or partly in H_2O; it is, however, certain that (if the composition stated above is correct) some hydrogens are attached to oxygens taking part in the Si—O chains.

Though the atomic positions are only known approximately as yet, they give reasonable interatomic distances and satisfactory agreement between observed and calculated *F*'s. The proposed structure accounts for both the platy and the fibrous character of the crystals. It also explains the observations of Kalousek[4] on the synthesis of the material from lime and silica; he found that the initial products up to about 100° C. were fibrous, and changed only slowly and at slightly higher temperatures into the platy tobermorite. Further, it allows a very natural explanation of the shrinkage of the (002) spacing which has been observed on dehydration[1], since removal of OH or H_2O from the grooves would permit two adjacent layers to pack together with their ridges interleaved instead of superimposed, while still leaving sufficient room to accommodate a calcium atom between them.

Further work is in progress, and it is hoped to obtain more accurate values of the atomic coordinates. We are very grateful to the Cement and Concrete Association for a grant to one of us (C. H. K.) which has made this work possible.

The Gas-Multiplier: a New Type of Electron Multiplier

I have recently investigated the possibility of using the Townsend electron avalanche process in a gas in a stage-by-stage system to give a highly stable electron-multiplication factor, and have constructed for this purpose a new form of electron-multiplier referred to as a gas-multiplier[1]. This device is designed to permit electron-multiplication by the Townsend α-process, while restricting the accompanying processes which cause positive feedback by releasing further electrons in the input region. As is well known, the latter processes, particularly photoelectric effects and positive ion bombardment of the cathode, have set an upper limit of about 10^4 to the gas-amplification which has been practicable in single-stage devices such as proportional counters and gas-filled photoelectric cells, owing to the imminence of breakdown. The gas-multiplier is designed to be free from this limitation, by operating under conditions that are stable for any number of stages.

The chamber containing the gas is divided into stages by the electrodes, which are plane, parallel and equally spaced. The application of a specified voltage per stage therefore gives a uniform field throughout the working volume of the multiplier. The only communication between one stage and the next is through holes in a central circular area in the intervening electrode. These holes are small, closely spaced, and uniformly distributed, and occupy a fraction *B* of the total working area. The thickness of the electrodes is made small compared with the diameter of the holes, to avoid distortion of the field, and as an approximation each electrode may be taken to intercept all but a fraction *B* of all particles or photons approaching it from either side. This assumes that the gas pressure is sufficiently low and the hole-pattern sufficiently fine for the scattering action of the gas molecules to spread the electrons or ions from a particular hole laterally over several hole-spacings in crossing a stage. It also assumes that the coefficient of light reflexion at the surfaces is low, and that there is no systematic alignment of the holes in successive electrodes, which is ensured by using a suitable random method of arrangement.

There are two essential conditions for a satisfactory margin of stability in the operation of the multiplier. The first is that each stage should have a suitable margin of stability by itself, that is, with no voltage on the others, and this requires $\gamma \exp \alpha S \ll 1$, where α and γ are the usual Townsend coefficients, and *S* is the spacing between electrodes. The second condition is that in operation the flux of positive ions and of photons reaching a stage from a later stage should decrease markedly as the number of stages intervening increases, so that the total feedback does not greatly exceed that in the stage itself. Assuming that there is no appreciable ionization in the gas by positive ions at the field-strength and gas-pressure in use, the ratio of total flux to internal flux can be shown not to exceed $\frac{1}{1 - GB}$, for any number of stages, where *G* is the gain per stage. It is therefore desirable that *GB* should not be greater than $\frac{1}{2}$, say. Provided that both the above conditions are satisfied, the feedback present has only a small effect on the gain, and, neglecting edge effects, *G* is approximately equal to $B \exp \alpha S$.

Table 1 shows a set of operating conditions used and the results observed. These results refer only to a preliminary experiment which was made to demonstrate the action of the multiplier, and was not designed to provide accurate measurements under closely controlled conditions. The rise- and decay-time is considered to be mainly due to the collection of the positive ions in the last stage. No appreciable delay or distortion other than this was observed as the number of stages was increased, provided that the output current did not exceed the value stated, which is of the order at which space-

Table 1

Diameter of perforated areas	3·81 cm.

A Film Radiometer for Centimetre Wave-lengths

THERMAL methods for the measurement of power at centimetre wave-lengths normally involve a substitution process in which the high-frequency power is assumed to be identical in magnitude with the d.c. power causing the same rise in temperature or change in resistance. While in some techniques this assumption results in no appreciable error, it is a general limitation of thermal methods that the high-frequency and d.c. powers are not dissipated in precisely the same manner. This feature of existing methods is particularly evident at low power-levels, of the order of 1 milliwatt, at wave-lengths of 3 cm. and less. Although a calibration of centimetre-wave milliwattmeters can be made against standard equipment operating at higher power-levels, this operation requires much auxiliary apparatus and attenuation measurements of high precision. There is a need, therefore, for further convenient power-measuring techniques at the milliwatt-level in which the limitations inherent in existing methods are avoided. It seems probable that a form of film radiometer or bolometer, in which the ideal of accurate substitution of d.c. power for high-frequency power is approached very closely, will fulfil these requirements; the results of some preliminary experiments in the development of such an instrument are summarized in this communication.

Very few direct measurements of power at centimetre wave-lengths using resistive films appear to have been made, and the only published information of which I am aware relates to extended films placed along the axis of a waveguide[1,2]. It has been known for some time, however, that a thin transverse film having a surface resistivity equal to the wave impedance of the waveguide forms a reflexion-less termination when followed at a distance of $\lambda_g/4$ by a perfect reflector (λ_g being the wave-length in the guide), and a modification of this arrangement is described below.

The problem of ensuring equivalent heating effects of high-frequency and d.c. power is obviously still considerable in a resistive film extending across the waveguide; fortunately, it is still possible to terminate a rectangular waveguide in its characteristic impedance by the use of a relatively narrow strip extending across the waveguide from the centre of the broad face. Such a strip is located in a region of very nearly uniform transverse electric and magnetic fields for the dominant or H_{01} mode, and the difficulty of attaching suitable d.c. connexions is at the same time much reduced. In the present experiments, a strip 0·35 cm. wide of surface resistivity 180 ohms per square has been used in a standard 3-cm. band waveguide, so giving a d.c. resistance of approximately 500 ohms between top and bottom edges of the strip. Impedance measurements confirm that the strip behaves, to a close approximation, as a pure shunt resistance. In addition, with the reflecting plunger fixed at a distance of $\lambda_g/4$ at a mid-band wave-length of 3·2 cm., an input-voltage standing-wave ratio of 0·9 or better can be achieved over a 10 per cent band-width by preliminary adjustments of width of film. The strip is insulated from the waveguide at one end and can be connected in a d.c. circuit for calibration purposes.

Theoretically, either changes of resistance or a rise in temperature can be observed; so far, only the latter quantity has been determined by the simple method of attaching a single copper – eureka thermocouple to the centre of the strip with the wires of the couple fixed at right angles to the electric field of the H_{01} mode. A similar thermocouple is placed on the external wall of the waveguide close to the strip, and a steady-state deflexion of about 10 cm. per mW. is obtained on a galvanometer scale after a period of one to two minutes.

Preliminary comparisons, at power-levels of 2–3 mW., with other calibrated equipment have shown that the errors in a d.c. calibration of the instrument are probably not more than a few per cent. Further experiments, using metallic films deposited on mica, are in progress in order to investigate the full possibilities of this form of film radiometer, and a complete account of the work will be published in due course.

I am indebted to Dr. J. A. Saxton for advice in the preparation of this communication. The work described was carried out as part of the programme of the Radio Research Board, and is published by permission of the Director of Radio Research of the Department of Scientific and Industrial Research.

Metal-catalysed Hydrolysis of Thiophosphoric Esters

STUDIES on the hydrolysis of parathion (O-O-diethyl-O-*p*-nitrophenylphosphorothionate) and E.P.N. (thiono-benzene phosphoric acid O-ethyl-O-*p*-nitrophenylester) at *p*H 7 showed unexpectedly that traces of some metal ions, for example, cupric ions, have a marked catalytic effect.

At *p*H 7·8–8·6, at which the measurements were made, the catalysis of the hydrolysis by hydroxyl ions is negligible, so that we have primarily reaction with water. The reaction was followed at 40° C. by measuring as a function of time the optical density of the liberated nitrophenolate in a Beckman spectrophotometer *D.U.*

Assuming a reaction of the first order, we obtain from the general formula for the velocity constant $(k=(1/t)\ln a/(a-x))$, $k=(1/t)\ln(D_\infty - D_0)/(D_\infty - D_t)$, where D_0, D_t and D_∞ are the optical densities at times 0, t and infinity[1].

The buffer solution used was borax–hydrochloric acid (conc. borax ± 0·03 mol./l.). Addition of 20 per cent ethanol in the case of parathion and of 40 per cent for E.P.N. was necessary because of the limited solubility of these compounds in water. Great care was taken to avoid impurities, as it proved that metals even catalysed in concentrations of 10^{-8} mol./l.

The reagents used were analytical grade; we are indebted to the American Cyanamid Co. and the Dupont de Nemours Corporation for providing

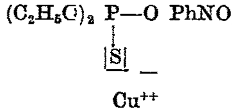
Control solution (complexon)	$0{\cdot}113 \times 10^{-3}$	8·55	$0{\cdot}75 \times 10^{-4}$	1·0

purified samples of parathion and E.P.N. Water, ethanol and hydrochloric acid were redistilled in an all-glass apparatus. All glassware was meticulously cleaned with a complexon solution (disodium-ethylenediamine tetraacetic acid) and with redistilled water.

The volumetric flasks in which the reaction took place were allowed to stand with buffer solution for several days. During the reaction the solutions were kept in the dark.

With these precautions, it was possible to obtain consistent results in each run. However, the use of a newly prepared buffer solution led to slightly different rate-constants (mean deviation ± 10 per cent) without altering the general picture of the catalysis. As reference we used a solution containing 10^{-3} mol./l. of complexon III, to bring down the concentration of most metal ions present as impurities to less than 10^{-15} mol./l. With the concentrations of cupric ions used, no hydroxide formation could be detected, in agreement with the solubility data given by Seidell[2]. The results are shown in Table 1.

When the effect was first found, it was thought that it might be due to the catalytic oxidation of parathion to paraoxon—the oxygen analogue of parathion[3]. This, however, was not the case, as the hydrolysis constant of paraoxon (see Table 1) is lower than the copper-catalysed hydrolysis of parathion. (The effect of cupric ions on the hydrolysis of paraoxon is very small.) Moreover, an experiment in which oxygen was meticulously excluded by keeping the solution under high vacuum ($\sim 10^{-4}$ mm. mercury) showed that the catalysis continued. The effect of other ions (magnesium, calcium, barium, aluminium, cobalt, cadmium and silver) was also investigated. In a glass vessel there was a marked enhancement of the hydrolysis. As we found very little variation of the reaction velocity with the metal ion concentration, the reaction was also measured in a polyethylene flask. Only in the case of copper ions was catalytic action found. The other metals investigated showed about the same velocity as the reference solution (with added complexon) in glass. The cause of this behaviour is being investigated, especially whether there is a real heterogeneous catalysis or if copper ions are liberated from the glass by absorption of other ions. In alkaline hydrolysis of parathion, cupric ions had no catalytic effect. To explain this phenomenon complex formation in much the same way as recently assumed by Wagner-Jauregg[4] for the hydrolysis of di*iso*propylphosphorofluoridate may be considered.



$$(C_2H_5O)_2\,\overset{+}{P}\text{—O PhNO}_2 \quad \begin{matrix} | \\ |\underline{S}|\,\overline{} \\ Cu^{++} \end{matrix}$$

Such a complex will have a more polar P—S bond and as a consequence will show more 'opposing resonance' and a reduced stability.

It is well known that thiophosphoric esters form complexes with salts of heavy metals[5]. An unexplained fact so far is the obvious specificity of cupric ions. It may well be that this type of catalysis, which occurs at very low concentrations, plays an important part in the degradation of spray residues.

Paper Chromatographic Identification of the 2 : 4-Dinitrophenyl-Derivatives of Aliphatic Amines

DURING recent work on the structure of bacitracin *A*, the identity of small amounts of aliphatic amines was confirmed by allowing them to react with 1 : 2 : 4-fluorodinitrobenzene[1] and chromatographing the resulting dinitrophenyl derivatives on paper[2]. A number of primary aliphatic amines can readily be separated by chromatography on paper[3], or by ionophoresis on paper at pH 7 using collidine acetate buffer[2,4], and the spots revealed with ninhydrin. Schwyzer has separated certain primary, secondary and tertiary amines by paper chromatography, the spots being revealed by spraying with an indicator[5]. However, in view of the fact that the technique described here will give further evidence of the nature of a mixture of primary and secondary amines and ammonia, and that 0·5 µgm. or less of the dinitrophenyl-amines can be detected on the chromatograms under ultra-violet light, it seemed worth while to place it on record.

A small sample of the amine is allowed to react with 1 : 2 : 4-fluorodinitrobenzene and the dinitrophenyl-derivative is identified by reversed-phase chromatography on paper. In a typical experiment, fluorodinitrobenzene (0·15 µl.) in 0·2 ml. of ethanol was added to 10 µgm. of the amine or its hydrochloride in 0·1 ml. water, followed by 0·2 *N* sodium bicarbonate solution (0·1 ml.). After standing for 15 min. at room temperature, the solution was placed at 105° in a sealed tube for 2 hr. Excess fluorodinitrobenzene was removed by addition of a solution of glycine (0·1 ml. containing 300 µgm.) and allowing the mixture to stand for 2 hr. at room temperature[6]. Ethanol was then removed in a vacuum desiccator, 0·15 ml. of 0·2 *N* sodium bicarbonate solution added and the dinitrophenyl-amines extracted into ether. The residue obtained on evaporation of the ether solution was dissolved in 5 µl. ethanol and 1·7 µl. of the solution applied to a paper chromatogram. Whatman No. 1 paper treated with Dow Corning silicone No. 1107[7] was used and the chromatograms were developed with the more polar phase obtained on mixing methanol, chloroform and water (10 : 10 : 6 by volume). The chromatograms were run as recommended by Kritchevsky and Tiselius[7] and allowed to develop for 16 hr., when the solvent front had run off the bottom of the sheet (35 cm. long). 2 : 4-Dinitroaniline (R_F, 0·60) had then travelled 26·25 cm. The values of R_A (defined as the ratio of the distance moved by the substance to the distance moved by 2 : 4-dinitroaniline) and of R_F for the dinitrophenyl-derivatives of the amines used are shown in Table 1.

Table 1. Behaviour of Dinitrophenyl-Amines on Paper Chromatograms

$$R_A = \frac{\text{Distance moved by substance}}{\text{Distance moved by 2 : 4-dinitroaniline}}$$

Dinitrophenyl-derivative of	R_A	R_F
Ammonia	1·00	0·60
Methylamine	0·88	0·53
Dimethylamine	0·80	0·48
Ethylamine	0·67	0·40
*iso*Propylamine	0·47	0·28
Diethylamine	0·44	0·26
*iso*Butylamine	0·33	0·20
*iso*Amylamine	0·20	0·12
*iso*Hexylamine	0·12	0·07

By plotting the values of $R_M \left[= \log_{10} \left(\frac{1}{R_F} - 1 \right) \right]$ for the dinitrophenyl-derivatives of the primary and secondary amines against the number of methylene groups in the amines, two parallel straight lines are obtained for the two homologous series (cf. Bate-Smith and Westall[8]).

With the small spots applied to the chromatograms, all the dinitrophenyl-amines listed are separated from each other except the derivatives of *iso*propylamine and diethylamine. These two substances can be separated by prolonged development of the chromatogram. The spots can easily be eluted from the appropriate areas of the chromatograms with 3 ml. of ethanol. Measurement of the optical density of the resulting solutions at 345 mµ shows that the primary and secondary amines used have reacted almost quantitatively with 1 : 2 : 4-fluorodinitrobenzene. Ammonia gives only about 50 per cent of the expected yield and the high temperature used for the reaction is required to obtain this yield. The low solubility of the dinitrophenyl-derivative of methylamine in ethanol may also result in low recoveries in certain cases. Where an elongated spot due to dinitrophenyl-methylamine will not interfere with other substances, the spots may be applied to the chromatogram in ethanol–acetone (1 : 1) instead of ethanol. The theoretical recovery of dinitrophenylmethylamine is then obtained. The method therefore appears to have potentialities as a semi-quantitative tool.

Since the dinitrophenyl derivatives of the primary aliphatic amines show an absorption maximum at 345 mµ, while the corresponding derivatives of secondary amines show a maximum at 365–370 mµ, the measurement of the optical density of an eluate at two wave-lengths provides corroborative evidence as to whether the substance is derived from a primary or secondary amine.

Erosion in Meanders

In connexion with the communication by J. H. Horlock in *Nature* of November 26, p. 1034, I am writing to urge that the term 'meander' should be strictly limited to natural meanders, not to bends due to secondary flows. The term 'meander' is derived from the River Meander, which swings from bank to bank in an almost perfect pattern. The Central Board of Irrigation, India[1], many years ago defined "a meandering river as a river which follows a sinuous path due to natural physical causes, not imposed by external restraint". The experiments quoted were carried out under very unnatural conditions and hence produced highly unnatural results.

C. C. Inglis
(Director)

Hydraulics Research Station,
Howbery Park,
Wallingford, Berks.

[1] See "The Behaviour and Control of Rivers and Canals (with the aid of Models)"; obtainable from Publications Branch, General Department, India House, Aldwych, W.C.2. 13*s*.

I am grateful to Sir Claude Inglis for pointing out that the term 'meander' should be restricted to bends similar to natural meanders. I agree that the initial shapes of the bends used in the experiments described in my communication were not true meanders; but the point of the experiment was to demonstrate that the nature of the erosion in such bends would depend largely on the initial curvature at entry to the bend. Such artificial bends probably develop into natural meanders. Subsequent experiments on natural meanders of similar amplitude and wave-length show that erosion occurs on the banks on the outside of the bends, and not on one bank, as in the original experiments with artificial bends.

J. H. Horlock

Engineering Laboratory,
Cambridge.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 27

London School of Economics and Political Science (at Houghton Street, Aldwych, London, W.C.2), at 5 p m.—Prof. Morris Ginsberg: "Reason and Experience in Ethics".*

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Prof. Glenn Sonnedecker (U.S.A.): "Structure and Stresses of American Pharmacy".

Royal Institute of Chemistry, London Section (joint meeting with the Woolwich Polytechnic Scientific Society, at the Woolwich Polytechnic, London, S.W.18), at 7.30 p.m —Dr. J. W. Rodgers: "The Extraction and Uses of Titanium and Zirconium".

Tuesday, February 28

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. H. Judith Grenville-Wells: "Crystals, Temporary and Permanent: (2) Diamond".*

Institution of Electrical Engineers, Measurement and Supply Sections (at Savoy Place, London, W C 2), at 5.30 p.m.—Mr. M. W. Makowski and Mr. K. Mochlinski: "An Evaluation of Two Rapid Methods of Assessing the Thermal Resistivity of Soil".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p m.—Dr. J. M. Zarek: "General Biomechanics".*

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. Anthony J. Barrett: "Use of Elementary Plasticity in Design".

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1); at 7 p.m.—Mr. B. J. Terrell: "Measurement of Angular Speed".

Wednesday, February 29

Society for Analytical Chemistry (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 4.30 p.m —Annual General Meeting. 5 p.m —Sir William Slater: "The Evolution of Agricultural Research" (Bernard Dyer Memorial Lecture).

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 30 p.m.—Discussion on "Technique of Microwave Measurements", opened by Mr. E. M. Wareham.

Society of Chemical Industry, Food Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m — Dr. N. Uri: "Some New Aspects of the Mechanism of Fat Oxidation and Its Inhibition".

Thursday, March 1

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. A. J. Arkell: "Boats and Pyramids in Ancient Egypt".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Geoffrey Taylor, F.R.S.: "Fluid Flow in Regions Bounded by Porous Surfaces"; Mr. C. N. Davies and Mr. C. V. Peetz: "Impingement of Particles on a Transverse Cylinder".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. S. Brian Kendall: "Host-parasite Relationships between Liver-flukes and *Lymnaeidae*"; Dr. L. P. Joyner and Dr. S. Brian Kendall: "Potentiation of the Coccidiostatic Activity of Sulphonamides by Pyrimethamine".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5 30 p.m.—Discussion on "Recruitment in the Engineering Profession".

University College, London (in the Chemistry Theatre, Gower Street, London, W.C.1), at 5.30 p m.—Dr. R. S. Nyholm: "The Renaissance of Inorganic Chemistry" (Inaugural Lecture).*

Cement and Concrete Association (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. T. C. Powers (U.S.A.): "Physical Structure and Engineering Properties of Concrete".

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. E. S. Moult: "Power Plants for Supersonic Flight".

Friday, March 2

Association of Applied Biologists (in the Meeting Room of the Royal Entomological Society of London, 41 Queen's Gate, South Kensington, London, S.W.7), at 10.45 a.m.—Meeting on "Clover Seed Production".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Arthur Bryant. "Samuel Pepys".

Saturday, March 3

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. D. Chilton: "The Weather Glass".*

British Interplanetary Society (in the York Hall of Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Prof. A. D. Baxter. "Combustion Chambers for Rocket Engines".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Electrical Engineering—The Secretary of University Court, The University, Glasgow (February 29).

Senior Lecturer in Chemistry at Birkenhead Technical College—The Director of Education, 63 Hamilton Square, Birkenhead (February 29).

Senior Research Fellow (with an honours B.Sc. degree in chemistry or biochemistry and research experience) to work in the Department of Biological Chemistry on the chemical aspects of a research programme concerned with the fluorescent labelling of proteins, carried out jointly by the Departments of Pathology, Bacteriology and Biological Chemistry—The Secretary, The University, Aberdeen (February 29).

Computer (preferably graduate) for skilled work in mathematical statistics and some applied mathematics—The Registrar, King's College, Newcastle-upon-Tyne (March 3)

Assistant (with special interests in vertebrate palæontology) in the Department of Geology in St. Salvator's College, St. Andrews—Joint Clerk to the University Court, The University, College Gate, St. Andrews (March 9).

Scientific Officer and Experimental or Assistant Experimental Officer in the Brown Trout Research Laboratory, Pitlochry, for duties chiefly concerned with salmon research—The Establishment Officer, Scottish Home Department, Room 364, St. Andrew's House, Edinburgh 1 (March 10).

Assistant Experimental Officer (with a pass B.Sc. degree or equivalent) in the Department of Potato Genetics, for general maintenance of stocks and tests for resistance of tuberous Solanums—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (March 12).

Demonstrator in Geography—The Registrar, University College of North Staffordshire, Keele, Staffs (March 12).

Microbiologist (Scientific Officer or Senior Scientific Officer grade), to undertake investigations of the microflora, mainly that of the fungal microflora of the roots of grassland species during their growth and decay—The Secretary, Grassland Research Institute, Hurley, Maidenhead (March 12).

Lecturer (with a special qualification in algebra and/or geometry) in the Department of Mathematics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 13).

Research Fellow in Cosmic Rays for work which will be concerned largely with time variations of intensity and the origin of cosmic rays—The Registrar, University of Tasmania, Box 647C, G.P.O., Hobart, Tasmania (March 15).

Assistant (preferably with a degree in one of the natural sciences) in Charge of the Natural Sciences Library—The Registrar, University College, Singleton Park, Swansea (March 17).

International Wool Secretariat Research Fellow (microbiologist or bacteriologist), for work on the interconversion of steroids and triterpenes—The Registrar, The University, Leeds 2 (March 17).

Lecturer in Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (March 17).

Lecturer in Experimental Pharmacology—Secretary of University Court, The University, Glasgow (March 17).

Lecturer (with a good honours degree in geography) in Geography in St. Salvator's College—Joint Clerk to the University Court, The University, College Gate, St. Andrews (March 17).

Senior Research Fellow (graduate in science or chemical engineering, with experience in coal research) in Coal Research, at the University of Sydney, Australia, to plan and undertake research on occurrence, nature or utilization of coal—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (Australia, March 17).

Senior Lecturer (with a degree in metallurgy or equivalent, and industrial and research experience) in Metallurgy—The Registrar, College of Technology, Manchester 1 (March 19).

Metallurgist or Metal Physicist (with a first- or second-class honours degree or equivalent), and an Inorganic Chemist (with a first- or second-class honours degree or equivalent), in the Metallurgy Division, National Physical Laboratory, Teddington, Middlesex, for work on new analytical techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.65/6A (March 28).

Lecturer (with experience either in theoretical or experimental physics) in the Department of Physics—The Registrar, The University, Liverpool (March 29).

Assistant Lecturers (2) (one in pure, the other in applied mathematics) in Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (March 30).

Head (with good academic qualifications and teaching and/or industrial experience) of the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1 (March 30).

G. F. Grant Chair of Chemistry—The Registrar, The University, Hull (March 31).

Lecturer in Mechanical Engineering—Joint Clerk to the University Court, Queen's College, Dundee (March 31)

Lecturer (with special qualifications in physical chemistry) in Chemistry at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31).

Technician in the Department of Zoology—The Secretary, The University, Exeter (March 31).

Lecturer or Assistant Lecturer in Statistics—The Registrar, The University, Leeds 2 (April 2)

Turner and Newall Research Fellows in Engineering, Inorganic Chemistry, Physics and Allied Subjects—The Registrar The University, Manchester (April 30)

Bacteriologist (graduate with some general bacteriological experience), for work on phage-typing of staphylococci, with a view to taking responsibility, under the Director, for the routine typing service—The Director, Central Public Health Laboratory, Colindale, London, N.W.9.

Biochemist (with a first- or second-class honours degree in biochemistry or equivalent qualification, and postgraduate research experience), to assist in the study of certain physico-chemical properties of mucin—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 56/3.

Brush Research Fellow (honours graduate in science or engineering), for research in the mechanical and electrical aspects of power generation control and utilization—The Registrar, The University, Nottingham.

Demonstrator (with a wide practical knowledge of microbiological techniques and preferably with experience in the food or fermentation industries), for work associated with teaching of practical microbiology—The Secretary. The Royal Technical College. Glasgow, C.1.

Electroencephalograph Recordist (Grade 1)—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Lecturer (Grade I) in the Department of Zoology at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Lecturer in Physics, with special reference to the physics of nuclear reactors—The Registrar, The University, Birmingham 15.

Lecturer (with an honours degree in physics together with suitable teaching experience) in Physics—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

Lecturers (2) (with research interests in applied mathematics, preferably in fluid dynamics) in Mathematics—The Secretary, The Royal Technical College, Glasgow.

Master to teach Mathematics up to advanced level standard—The Director of Studies, Nautical College, Pangbourne, Berkshire.

Master (under 35, with Oxford or Cambridge degree) to teach Biology (mainly botany) with subsidiary chemistry—The Headmaster, The College, Winchester.

Principal Lecturer (with high academic qualifications and preferably some industrial experience) in Food Science—The Secretary-Treasurer, Royal Technical College, George Street, Glasgow, C.1.

Scientific Officer (with an honours degree in biochemistry or physiology, and preferably with previous experience in biological research) in the Nutrition Department, to take part in work that will include the determination of the biological value of proteins, the study of calcium and phosphorus metabolism including the use of radioactive tracers, vitamin A and D assays and general nutritional experiments with rats—The Secretary, National Institute for Research in Dairying, Shinfield, near Reading, quoting 56/5.

Scientific Secretary (with a first- or second-class honours degree in agriculture or other natural science with at least three years appropriate postgraduate experience and some administrative experience) to the Director of the West African Cocoa Research Institute, Gold Coast, to assist the Director in the work of the Institute including technical correspondence, preparation of reports and publications, minutes and other technical matters—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.197/200/012.

Senior Lecturer in Physiology and Pharmacology, at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

Senior Lecturer (with a good honours degree and design experience in nuclear power plant) in Nuclear Power Engineering—The Secretary, The Royal Technical College, Glasgow.

DIFCO

DIFFERENTIAL MEDIA

BACTO-RUSSELL DOUBLE SUGAR AGAR
—a useful aid in identification of newly isolated strains of intestinal bacteria.

BACTO-KRUMWIEDE TRIPLE SUGAR AGAR
—an excellent medium for identification of intermediate strains of the colon-typhoid group.

BACTO-TRIPLE SUGAR IRON AGAR
—combines the fermentation reactions obtained on Krumwiede's Medium with hydrogen sulphide production.

BACTO-PHENOL RED MEDIA
—particularly adapted for determination of fermentation reactions of bacteria. Complete agar and broth media containing carbohydrates are available as are also the basic media without carbohydrate.

BACTO-PURPLE MEDIA
—basic media, excellently suited for addition of carbohydrate for study of bacterial fermentation at an acid reaction.

Sugar Phosphates

The following chemicals of English manufacture and to the specifications shown are now available :

α-D(+)-Glucose-1-phosphoric acid, dipotassium salt dihydrate
$C_6H_{11}O_5.O.PO_3K_2.2H_2O$ Mol. wt. 372.35
Assay (ex P and K) : Not less than 95.0%
Inorganic P : Not more than 0.1% (as P)
Loss on drying : Not more than 11.0% at 105° C in vacuo
$[\alpha]_D^{20}$=76° to 80° (c, 5 in water) 1 g—12s. 6d.

D(+)-Glucose-6-phosphoric acid, barium salt heptahydrate
$C_6H_{11}O_5.O.PO_3Ba.7H_2O$ Mol. wt. 521.60
Assay (ex P and Ba) . Not less than 95.0%
Inorganic P : Not more than 0.1% (as P)
Loss on drying Not more than 25.5% at 105° C. in vacuo
$[\alpha]_D^{20}$=20° to 22° (c, 5 in N/1 HCl) 0.1 g—8s. 6d. 1 g—50s. 0d.

Also available :

D(+)-Fructose-1 : 6-diphosphoric acid, dibarium salt
0.1 g—4s. 3d. 1 g—25s. 0d.

D(+)-Fructose-6-phosphoric acid, barium salt
0.1 g—5s. 6d. 1 g—42s. 6d.

Enquiries for larger quantities are welcomed.

PEACEFUL USES OF ATOMIC ENERGY

EVEN before the Conference on the Peaceful Uses of Atomic Energy met at Geneva in August last, negotiations were proceeding between several European countries with the view of establishing some system for nuclear energy co-operation. Provision for European co-operation in nuclear research was made in the European Organization for Nuclear Research, established by the Convention of July 1, 1953, and which was adopted by representatives of Belgium, Denmark, France, the German Federal Republic, Greece, Italy, Netherlands, Norway, Sweden, Switzerland, the United Kingdom and Yugoslavia. The Organization came into existence in 1954 with the ratification of the convention by Switzerland and six other nations, and the new institution, with an international laboratory and headquarters at Geneva, thereupon took over the work and documentation of the European Council for Nuclear Research, which had prepared the way for the founding of the new permanent organization.

A concise account of the development of the European Organization for Nuclear Research is given in an information pamphlet recently issued by the United Nations Educational, Scientific and Cultural Organization in the series "Unesco and its Programme"*. It is also described by Dr. L. Kowarski, director of the French Atomic Energy Commissariat, who was also director of the Laboratory Study Group which carried out that phase of the scientific work for the European Council for Nuclear Research, in an article, "The Making of CERN—an Experiment in Co-operation", contributed to the *Bulletin of the Atomic Scientists* of December 1955. Private conversations between European physicists took place as early as 1947, and in 1949 L. de Broglie was urging the creation of regional European research institutes in fields of this type. Proposals for co-operation in nuclear research, however, first took definite shape in June 1950, with Prof. I. I. Rabi's suggestion at Florence on behalf of Unesco for an inter-governmental conference on the subject.

The preliminary inquiries which resulted in the formation of the European Council were carried out by Unesco, and this project for co-operation in nuclear research may thus fairly be claimed by Unesco as one of its major achievements. The agreement of February 12, 1952, creating the Council was signed by nine countries: they did not include the United Kingdom, although the United Kingdom had been represented at the Conference of December 1951, when the preliminary arrangements were made, and the United Kingdom is, with France, the largest single contributor to the finances of the permanent organization. For the period 1953–56 it is bearing some 24 per cent of the cost of the Organization's activities, estimated at £10 million over the first seven years, a figure which the Council, of which Sir Ben Lockspeiser is chairman, decided in December to increase by about 40 per cent.

The Unesco pamphlet, which includes excerpts from the convention establishing the permanent organization, outlines the way in which the scientific study groups of the European Council for Nuclear Research clarified the problems in nuclear physics which could most usefully be examined at the international level, and defined the spheres of research within which co-operation between physicists and laboratories in different countries would be specially fruitful. These exchanges of views led to the decision to fix the energy of the proposed synchro-cyclotron for the international laboratory at 600 MeV. and that of the proton-synchrotron at greater than 25 GeV. The cost of building the laboratory and the machines accounts for more than 80 per cent of the Organization's estimated expenditure for the first seven years, and it is considered that its construction near Meyrin, close to Geneva and to the French frontier, will facilitate the creation of the intellectual atmosphere essential to such research as well as safeguard its international character.

The importance of this aspect is brought out particularly well in Dr. Kowarski's article, and he also emphasizes some of the staffing problems which such an organization inevitably encounters. The present staff of 285 is to be increased to 400 by 1956 and to 500 by 1960, and while a free flow of staff from member countries is expected, the general shortage of scientists is being kept in mind. The original director-general, Prof. F. Bloch, was succeeded in September 1955 by Prof. C. J. Bakker, to whose article in *Physics To-day* of September 1955, Dr. Kowarski refers those seeking technical details of the accelerators and buildings. He anticipates, however, that by late 1957 all major services will be installed on the Meyrin site, the cyclotron will be in the final stages of completion and the synchrotron well begun. The initial cosmic-ray programme should assist the starting-up of the instrumentation and, on a modest scale, the Organization will act as a European clearing house for such activities as the standardization of emulsion techniques. Apart from the small permanent staff, scientists are being invited to work at Meyrin for a limited period: for example, Prof. G. C. Wick and Prof. W. K. H. Pankofsky are spending one year there (see *Nature*, January 21, p. 117).

Dr. Kowarski's comment on the United Kingdom's decision to remain in the formal position of an observer should be noted by British readers of his article. That in practice Great Britain became also a keen debater and provided consultants, as well as taking a full share of the financial support, gave general satisfaction, and this has its bearing on the attitude of the British Government to co-operation with other European countries in the peaceful uses of nuclear energy. Questioned on this point in the House of Commons on February 1, Mr. R. A. Butler, the Lord Privy Seal, said that it is too soon to state what form British participation in such collaboration should take. While agreeing as to the importance of Britain becoming more closely associated with the project known as 'Euratom', Mr. Butler suggested that the proposals in the report on European collaboration in atomic energy issued by the working party on nuclear energy of the Organization for European Economic Co-operation* also required very close consideration.

---

* European Co-operation in Nuclear Research. (Unesco and Its Programme, No. 11.) Pp. 26. (Paris: Unesco; London: H.M. Stationery Office, 1954.) 1s. net.

This working party was asked to examine and report on the possible scope, form and methods of economic and financial co-operation in the use of nuclear energy; and it should be noted that the working party is no less convinced than those who elaborated the Euratom plan that some form of European co-operation is necessary. It is a matter of deciding the form which co-operation should take, and the report emphasizes that, apart from technical details relating to industrial secrets, all the techniques for the industrial processing of nuclear 'fuels' at all stages were made public at the Geneva Conference in August 1955, with the exception of isotope separation techniques.

In discussing the effort required to develop a European nuclear energy industry, the report stresses not only the capital expenditure still required but also the needs of equipment and the large number of technicians who must be trained. Except in the United Kingdom and in France, with its Saclay centre and the Marcoule pilot plant which began to operate in January, that effort is only in its infancy. The report estimates that within the next five years much of the capital invested in nuclear energy will be used for research, and that while, apart from the small percentage of nuclear physicists required, most of the industrial and nuclear chemists, metallurgists, electricians and nuclear-energy engineers can be recruited in industry and will require only a year's training to adapt themselves to routine work, four or five years are required to provide the nucleus of a research staff. Comparing the situation with that in the United States, it estimates European expenditure on nuclear energy as about 300 million dollars in 1955 compared with 2,000 million in the United States in 1954, and the numbers of technicians employed in nuclear energy as about 15,000 in the United States in 1955, 5,000 in the United Kingdom, 1,800 in France and barely 1,000 in the rest of Europe. Moreover, the number of science students enrolled in the United States in 1952 exceeded 500,000, compared with about 180,000 in Europe.

Taken as a whole, Europe's present nuclear effort falls far short of its industrial potential and the working party suggests that two bodies should be set up by the Organization for European Economic Co-operation. The first of these, a Steering Committee for Nuclear Energy, would be concerned with the co-ordination of plans and of national legislation, the promotion of joint undertakings, training and standardization and the encouragement of international trade. The working party does not, however, contemplate that the Organization would be concerned with scientific and technical information, as distinct from that of an economic or financial character; but it stresses the importance of creating a favourable climate in Europe for the establishment of a nuclear industry. The promotion of joint undertakings is regarded as particularly important and promising in that the demands of some undertakings even on the smallest possible scale, exceed the resources that individual countries could be expected to contribute. Apart from the hazardous nature of some undertakings, and consequent reluctance of a single country to assume the entire financial risk, production costs for some undertakings decrease rapidly as the size increases.

Of the types of joint undertaking which the working party contemplates, plant for separating isotopes is particularly stressed, and it is suggested that such an undertaking might attract the participation of the United Kingdom, on certain conditions. Chemical separation plants for irradiated fuels, the production of heavy water, the fabrication of 'fuel elements' from metal or oxide, plants for the conversion of ore into metal, and electric power stations and semi-industrial laboratories are other possibilities instanced; but the last two or three are only advocated when existing installations are working to full capacity. For the promotion of training, besides the co-ordination of lectures and training courses, the report suggests encouraging the exchange of teachers and students, the creation of scholarships and, possibly, the creation of a European centre for teaching nuclear science, to complete the training given in national centres.

One advantage of the joint undertaking is that it facilitates security control. This would be the main function of the Control Bureau, the second body which it is suggested the Organization for European Economic Co-operation should establish. The sole object of this control is to prevent fissile materials used in the joint undertakings or produced by them from being ultimately diverted to military purposes. It would be necessary, therefore, to establish effective control over each national undertaking using fissile material originating directly or indirectly from the joint undertakings. For this purpose an international control laboratory and a strict accounting system for the production and use of all fissile elements originating directly or indirectly from the joint undertakings would be essential, though the products of nationally owned factories would not be affected.

The report definitely contemplates that the control system which it recommends might prove the first step to a system of world control, and that the proposal is in fact compatible with the system of world control embodied in the project for an international agency which the United States has submitted to the United Nations. It meets, moreover, the stipulation for a guarantee of effective control over all joint activities which the working party believes to be the only condition on which the United States would co-operate fully in the supply of fissile materials, specialized equipment and manufacturing secrets.

---

* Possibilities of Action in the Field of Nuclear Energy. (Working Party on Nuclear Energy.) Pp. 70. (Paris: O.E.E.C.; London: H.M. Stationery Office, 1956.) 300 French francs; 6s.

On that ground alone the proposals in this report merit the most careful consideration, and the flexbility on which the working party insists and the fact that the proposal is freely open to European countries and not limited to the six countries of Euratom should commend it particularly to Britain. Euratom, it is true, is also anxious to secure the full participation of Great Britain in the proposed European Atomic Authority, nor is it intended to exclude other countries from the six original participants (France, Belgium, the German Federal Republic, Italy, Holland and Luxembourg). There are, indeed, broad similarities between the two schemes. That which M. Monnet is now pressing so firmly would make Euratom itself supranational by providing that the participating countries should delegate real powers to the European Atomic Energy Commission. It would be concerned solely with the development of atomic energy for peaceful purposes and it provides that all fissile material produced or mported by the importing countries shall become the property of the European Atomic Energy Commission, which alone would authorize the construction and operation of atomic installations. This, of ourse, implies the establishment of a security control ystem, the rules for which would be defined by the Commission in close co-operation with, for example, he United Nations; but the Commission itself would be responsible for seeing that these rules are applied.

A communiqué issued on February 12 by the Foreign Ministers of the six nations in the European Coal and Steel Community "confirmed the need and urgency to create a common European organization n the atomic field". It stated that the necessary directives have been given to the committee to complete its work as soon as possible and the Ministers believe the organization can be set up this year. The British Government, during the present meeting of the Organization for European Economic Co-operation, has stated that it is willing to lend all possible aid to the development of a European tomic energy pool.

There are two points which should here be noted. First, under either plan, the nuclear energy authority will come to grips at a supranational level with the establishment of an international control agency. This problem the Political Committee of the United Nations postponed for discussion at an international conference to be convened in the future. This was one, it is true, at the request of smaller countries ke Sweden; but as a result the establishment of Euratom or such a European Commission as M. Monnet urges may well prepare the way and demonstrate the practicability of control methods, which the United Nations might later be able to extend to he control of nuclear energy for military purposes lso.

The second point is that M. Monnet's scheme overomes the difficulty of including the German Federal Republic, which has renounced the right to make nuclear weapons, and those which have not. As Prof. W. Heisenberg, director of the Max Planck Institute for Physics and adviser on atomic energy to the Federal Government, told the Parliamentary and Scientific Committee on November 8, in his address on post-war scientific developments in Germany, Germany has had to start from scratch in nuclear physics, and post-war development has been slow. The European Organization for Nuclear Research has given valuable assistance, and several German research institutes are already assisting in construction at Meyrin; and when this is complete, the German universities and engineering colleges hope to participate in research there.

The main difficulty in planning such a programme in Germany is the lack of man-power. There are no trained engineers and very few scientists trained to work in this field of nuclear power. The one advantage is the existence of colleges of engineering; but they have still to be suitably staffed. Development is likely to be very slow, although Germany is extremely anxious to co-operate with the Western countries and to send young scientists and technicians to Great Britain and elsewhere for training, as well as to establish scientific stations for reactors. Nevertheless, it has since become apparent that, while desiring free agreement with the United States for the import of uranium and close co-operation with Britain in the industrial exploitation of nuclear power, German industry does not favour a supranational authority but only a co-ordinating committee.

Prof. Heisenberg indicated to the Parliamentary and Scientific Committee that the German Government is prepared to entrust the development of nuclear science mainly to private industry. Since, however, Dr. Adenauer and some of his ministers firmly support M. Monnet's plan for Euratom, difficulties may well arise if German industry maintains such an attitude; and it would seem that the attitude of Great Britain could be an important factor in determining the success or failure of proposals for a European nuclear community, though full British participation in such a community as M. Monnet's Committee proposes seems unlikely.

These are sufficient reasons for welcoming the outlook implied in the reference which Sir Anthony Eden made in his broadcast speech on January 22 to the possibility that nuclear power would transform the whole future of the world as fully as the discovery of the steam engine. Whether this is true or not, the implications of nuclear energy for the economy of Great Britain and its potentialities require very careful and close consideration. On the economic plane, for example, it is understood that experts are thinking in terms of an export trade for British nuclear energy industry of at least £300 million by 1975, with a home trade at a similar figure. Even when due regard is had to the fact that much of this export trade will be within the Commonwealth, where for a long time to come the United Kingdom is likely to supply uranium in return for the uranium oxide and to re-process the burnt elements from reactors, we cannot ignore proposals which may foster a free market in nuclear energy or which bear closely on the development of the backward areas of the world.

Within the British Commonwealth itself, there are already many valuable outlets for the utilization of nuclear energy as a source of power: the copper mines of Northern Rhodesia, the iron ore deposits in Nigeria and the bauxite deposits in Western Australia may be quoted. Major developments within the Commonwealth are in Canada, where in addition to the two earlier research reactors, a new reactor, costing more than £12 million, will provide some of the best research facilities in the world; further, the Australian Government in July 1955 placed a contract of £750,000 with a British company for the design and supply of a research reactor near Sydney as the basis of a £4 million plan to develop nuclear energy for industrial purposes; and Pakistan has established an institute for nuclear energy and India hopes to build an experimental reactor near Bombay within two years. Nevertheless, the United Kingdom's contribution is likely to be large for many years, and particularly in the supply of small reactors of 5–10 megawatts. Since then, it has been announced that an American and a British firm have agreed to collaborate in the manufacture of reactors, and that another British firm is to build an experimental reactor for which the Atomic Energy Authority will provide the fissile fuel.

Such possibilities bear closely on the demands for materials and power which the developing industry makes within Britain itself. Already since the end of the Second World War, £100 million has been spent on the establishments at Capenhurst, Springfields and Windscale. The first of the new nuclear power stations at Calder Hall is expected to come into operation on October 17, and the second within the next six months. Six more reactors, with a total capacity of about 200 MW., should be operating in 1959 or 1960, and although the cost of these power stations is approximately double that of coal-fired generating stations, within ten years it may well be one-third that of the coal-fired station. Moreover, apart from the demand which the nuclear power stations make for the services of technicians and technologists, they are likely to have a considerable effect on the total labour supply required. Only a few hundred men are expected to be employed at the first of the new power stations, instead of the 2,500 men required to provide a conventional power station of the same size with coal alone. Less than 100,000 men will in fact be required to generate the same amount of energy in nuclear power stations of these first experimental designs, instead of the 700,000 men required to supply the coal which conventional power stations would need.

It is clear that we are not only faced with a challenge to shape technical and technological education to meet those needs, but equally with a challenge to face the implications for industry and society in general. These are problems which not merely the Government but industry also has to face—no less on the trade union side than on that of management. The potentialities for increased productivity are not limited to power supply alone. They reach far into other kinds of industry, and if they are to be realized, a new and more imaginative outlook, a greater flexibility and adaptability will be required of all engaged in industry at whatever level. With its plans for seeing that industry is supplied with the technicians, the technologists and the scientists that are needed to-day, the Government should also be planning to ease the process of adjustment and to deal with the changes in the pattern of society as well as of industry that may be required; and to foster the outlook and attitude to change which a wise system of education itself can best encourage.

SPRINGBOARD FOR SUPERSONIC FLIGHT

Thermodynamics and Physics of Matter

Edited by Frederick D. Rossini. (High Speed Aerodynamics and Jet Propulsion—Vol. 1.) Pp. xviii + 812. (Princeton, N.J.: Princeton University Press London: Oxford University Press, 1955.) 100*s.* net

THIS publication, a massive volume of 812 pages is only the first of a series of twelve books planned by a board of editors composed of Theodore von Kármán, Hugh L. Dryden and Hugh S. Taylor assisted at various times by the general editors Joseph V. Charyk and Martin Summerfield. The scientific reputation of the members of this group is a sufficient guarantee of the quality of the contents of the books. Vol. 6, "General Theory of High Speed Aerodynamics", and Vol. 9, "Physical Measurements in Gas Dynamics and Combustion", have already appeared and have been reviewed in these columns (*Nature*, 176, 479 and 1040; 1955). The books are excellently printed by the Maple Press, Inc., of York Pennsylvania, and show what care is devoted to the typography of scientific books by the Princeton University Press. The volume at present unde review is edited by Frederick D. Rossini, of the Department of Chemistry of the Carnegie Institute of Technology, Pittsburgh, and he is to be complimented on the excellence of his accomplished work.

The complete series of twelve volumes is planned to describe recent advances in "High Speed Aerodynamics and Jet Propulsion", a topic which would be termed 'technology' by some and be placed outside the pale of 'pure science'. But it is to the credi of the creative thinking of the editorial board tha the first few volumes of the series are planned to b expositions of those fundamental aspects of physic which lie at the very roots of this relatively new branch of aeronautical engineering. To those wh know little or nothing of the wide ramifications o modern engineering science, the contents of thi introductory volume will come as a salutary shock. The advances made in high-speed flight during th past ten years or so have been very rapid and hav brought into sharp focus the need for producing a comprehensive account, not only of the advances themselves, but also of the fundamental aspects o science which have to be adduced to solve the problems that arise.

The twelve books represent the accumulated work of more than a hundred physicists, chemists, engineers and mathematicians. A programme as vast as this needs powerful sponsors, much financial support and considerable organizing ability. In fact, the series was sponsored and assisted by many departments of the United States Air Force, Navy and Army, and the administration and editorial functions of the undertaking were centred at Princeton University. Apart from this, the University contributed financially to the support of the project. Truly a 'combined operation'.

The opening section of the volume is on the fundamentals of thermodynamics and is a very interesting account covering 110 pages. The second section, covering about 130 pages, deals with quantum mechanics and application to molecular structure, and then there is a section on thermodynamic properties of real gases and mixtures of real gases, and one devoted to the properties of gases and gaseous mixtures. These are followed by sections on critical phenomena; the properties of liquids and liquid solutions; the properties of solids and solid solutions; relaxation phenomena in gases; gases at low densities; and the thermodynamics of irreversible processes. Each section is effectively a brief summary of much of the present knowledge in its own field; the expositions are not unduly discursive and are clearly written. The different parts of the publication are self-contained reviews which could easily serve as texts in fields other than that of high-speed flow and jet propulsion. A detailed scientific review of each of the sections would involve a width of knowledge covering vast fields of modern theoretical and experimental physics; but there is no doubt that the excellence of the books so far published matches that of the original conception.

Sheer size, however, sometimes appals, and the Princeton series may well oppress the spirit of a young engineer or scientist who comes fresh to high-speed flight and who searches for understanding. To any such person it should be emphasized that the books are really Goliath volumes of reference, and are not intended to replace, for example, the two smaller David volumes on "High Speed Flow", edited by Howarth, and the two ancillary volumes of "Tables" and "Graphs" edited by myself. There is no doubt, however, that, in the long run, the Princeton series will have beneficial effects on the development of the aeronautical sciences, and that they will act as a springboard for still further discoveries in high-speed aerodynamics and jet propulsion. In spite of this, Dædalus might well have groaned had he realized that his rudimentary experiments in flying would some day lead to the massive volumes of the Princeton series.

L. Rosenhead

ELECTRIC TRACTION ENGINEERING

Electric Traction Engineering

An Introduction. By E. A. Binney. (Cleaver-Hume Electrical Series—No. 10.) Pp. 224+7 plates. (London: Cleaver-Hume Press, Ltd., 1955.) 15*s.* net.

THE design of electric traction equipment does not attract the attention of authors to the same extent as do the spectacular developments that have taken place recently in other fields. Progress has for a number of years been chiefly in the direction of steady improvements to established practice rather than in any major advance. The development of the diesel-electric system, together with the recent use, on the Continent of Europe, of industrial frequency supply to the contact line, have resulted, however, in a re-orientation of thought. This and recent proposals in Britain have stimulated interest in the subject, and it seems probable that the near future will see considerable expansion of the industry. The present time, therefore, is opportune for the introduction of a book such as the one under review, written especially for the student and the young engineer starting a career in this field.

The history and development of the various systems are first traced briefly, and there is an outline of the work involved in the choice and design of rolling-stock equipment. The major part of the work is devoted to the design of traction motors and their gearing. The modern d.c. traction motor is a highly specialized machine owing to strict limitations of space and exacting conditions of performance, and the author very rightly devotes a considerable part of the book to it. There are also chapters on the single-phase a.c. motor, with its own special problems, and on the diesel-electric generator, another machine of special characteristics. On the mechanical side a section is devoted to gear calculations and a chapter to mechanical drives.

A further chapter is given to d.c. control systems. Power and control diagrams are dealt with, and the principles of interlocks and automatic acceleration explained in detail. The use of rotary amplifiers is briefly dealt with. The final chapter outlines project work, including the preparation of speed–time diagrams.

The book is adequately illustrated with diagrams and half-tone blocks and includes useful appendixes of symbols, mathematical expressions, and calculations on gears.

G. H. Platt

'PROJECT 6' OF THE AMERICAN PETROLEUM INSTITUTE

Hydrocarbons from Petroleum

The Fractionation, Analysis, Isolation, Purification, and Properties of Petroleum Hydrocarbons. (An account of the Work of the American Petroleum Institute Research Project 6, at the Carnegie Institute of Technology, Pittsburgh, Penn.) By Prof. Frederick D. Rossini, Beveridge J. Mair, and Anton J. Streiff. (American Chemical Society: Monograph Series—No. 121.) Pp. xvi+556. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1953.) 143*s.* net.

THE sponsorship of fundamental research has been an activity of the American Petroleum Institute since 1926. One of its earliest projects was that established at the National Bureau of Standards under Edward W. Washburn's direction, which has since become widely known as "Project 6". The aim set before the first small group of chemists in 1927 was, quite simply, "the separation, identification and determination of the chemical constituents of commercial petroleum fractions", and yet, at the time, the methods available for the separation or characterization of mixtures of closely similar substances were utterly inadequate for such an undertaking. Unless entirely new techniques could be devised, it was clearly hopeless to expect that much progress could be made towards even a partial solution of a problem so complex. This is the challenge that was accepted.

Project 6 is still in active operation. The achievements of its first twenty-five years have been assembled from scattered publications and set out in this monograph. The account which Frederick D. Rossini (director of the Project since 1934) and his associates have now presented is indeed monumental, for in fact the original objectives have been largely attained. The ten chapters with which the book begins deal very exhaustively with the fractionating processes that were employed and particularly with fractional distillation, of which the unexploited potentialities were quickly grasped. With a wealth of drawings and diagrams, the techniques and the apparatus used for the separation of more than a hundred and thirty different hydrocarbons from one representative crude petroleum are set forth; and most of these individual hydrocarbons were obtained far purer than they had ever been made before. Succeeding chapters deal equally exhaustively with the methods used by the workers on the Project for the characterization of these petroleum constituents, for the measurement of their absolute purities and for the determination of their physical properties. The precision they sought and reached in these measurements (for example, of freezing and boiling points) was without precedent, yet it has come to be accepted as standard for any work of a similar sort intended to be of lasting quality.

More than half the length of the monograph is devoted to descriptions of techniques devised by Rossini and his associates, which are classics of their kind. For many readers who are not specialists in petroleum technology, this will constitute the chief value of the book. For the petroleum chemist there are, in addition, chapters which deal with the hydrocarbon composition of the gasoline, kerosine, gas-oil and lubricant fractions; with the analysis of several representative crudes; and with the composition of distillates, alkylates and co-dimers.

A brief discussion of the work done in other laboratories on the composition of petroleum takes in minor constituents which contain other elements besides carbon and hydrogen, but is out of character with the book as a whole and scarcely adds to its usefulness. It is as the authoritative account of the accomplishments of a famous project that this book takes its place in the literature of petroleum.

THE AUTORADIOGRAPHER'S VADE-MECUM

Autoradiography in Biology and Medicine
By Prof. George A. Boyd. Pp. xiii+400. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.) 8.80 dollars.

AUTORADIOGRAPHY is an important tool in the workshop of the histologist and histochemist; the provision of an ever-increasing range of biologically significant compounds labelled with radioactive isotopes makes it an attractive method of study, and its relative cheapness and simplicity provide further appeal, if such were needed.

Any worker with average competence in normal histological and photographical methods can produce an autoradiograph. But, unlike the methods of histology and photography, the production of significant autoradiographs demands a much clearer knowledge of the possibilities and limitations of these apparently simple techniques. Some of the limitations—those of the mobility and diffusion of the complexes to be studied—are familiar to the histochemist; others—those of the type of photographic emulsion and its response to radiations of different nature and energy from elements which vary widely in their half-lives—are less familiar even to the expert photographer. Even though the desired result may be mainly a qualitative record of the distribution, the worker needs to know a good deal more of his material—histological, photographic and isotopic—than is apparent at first sight.

Prof. G. A. Boyd has set out to provide a vade-mecum for the histologist who wishes to work in this field. In the theoretical section of the book an elementary treatment of the theory of the photographic process leads up to a consideration of the characteristics of commercial and scientific emulsions and of their response to α-, β- and γ-radiation. A chapter on the autoradiographic image is followed by a study of the important question of resolution. Dosage and exposure time are then dealt with, and finally a valuable chapter discusses the sources of error in various stages of the process.

The second part of the book, entitled "Technique", is a 'cookery-book' presentation of the various special methods in sufficient detail to permit a worker who is quite unfamiliar with a method to reproduce it satisfactorily. More than half this part deals with various types of sections applied to liquid emulsions and to films on permeable and non-permeable bases; the remainder deals with less-familiar problems on specimens which are not flat and on the preparation of difficult material such as undecalcified bone and teeth. Much of it is evidently written from first-hand experience, and each recipe is followed by a brief discussion of its possibilities and limitations. One of the problems for the British worker is the constant reference to proprietary materials which may or may not be available in his country.

The last part includes a comprehensive bibliography to the end of 1952 and a series of cross-referencing indexes which provides a useful guide to the eight hundred references in this list. A supplementary bibliography of 129 titles brings the material up to date to the end of 1953.

The book is well produced and well illustrated, and its price is no more extravagant than that of most American publications these days. A somewhat staccato style in the theoretical sections does not make for smooth reading; but there are negligibly few errors in the text. The technique of a preliminary infiltration of thick emulsions with developer at low temperatures is not referred to; this is a useful method for producing uniform development in track autoradiography. My main regret is the deliberate omission of any reference to quantitative methods; if Prof. Boyd can take the opportunity of a second edition to bring his bibliography up to date and to include a section on quantitative autoradiography, he will still further increase the debt which we owe to him for the present volume.

John E. Harris

Colloque sur l'Acoustique des Orthoptères, Jouy-en-Josas (5–8 Avril, 1954)

Annales de l'Institut National de la Recherche Agronomique. Série *C*: Annales des Épiphyties. Par René-Guy Busnel. Pp. 448. (5e Année (trimestriel); Numéro hors Série.) (Paris: Institut National de la Recherche Agronomique, 1955.)

ALL the papers presented at the symposium on the acoustics of Orthoptera, held in France in April 1954, together with the subsequent discussions, have now been published as a supplementary volume in series *C* of the "Annales des Épiphyties". The meeting has already been reported in these columns by Prof. R. J. Pumphrey (*Nature*, 173, 1219; 1954), and thus it is only necessary to direct attention to certain features of the printed work.

The volume is divided into three sections: definitions, methods and techniques; acoustic emission of Orthoptera; and acoustic reception and behaviour. Of the seven papers comprising the first section, the one of most importance is that by S. Klein describing the ionic loudspeaker, a new tool of great interest in biological acoustics. The second section comprises ten papers on sound emission ranging from morphological description of the stridulatory apparatus to physical analysis of the sound, and indicates the magnitude of the problem from the physical point of view. The third section is the most important, containing in its six papers reviews by Prof. W. Jacobs and Prof. R. J. Pumphrey on behaviour and by Prof. H. Autrum on sense physiology. This latter paper emphasizes the paucity of knowledge of the acoustic receptors of the Orthoptera. Prof. Jacobs's paper treats the subject of the classification and analysis of the acoustic behaviour of Orthoptera by the analytical methods of Lorenz and Tinbergen, while Prof. Pumphrey stresses the need for examination of the functional importance of the phenomena.

The book will be valuable to workers as a reference to the main outlines of the problem, representing as it does preliminary work in this interesting field.

P. T. HASKELL

Minerals for Atomic Energy

A Guide to Exploration for Uranium, Thorium, and Beryllium. By Robert D. Nininger. Pp. xii+367. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1954.) 55*s*. net.

THIS is an authoritative handbook written primarily for professional and amateur prospectors. The text is in three parts, with sixteen appendixes. Part 1 is a description of the more important uranium, thorium and beryllium minerals; Part 2 a survey of the known producing-areas of the world and of potentially favourable localities; and Part 3 a review of prospecting techniques with advice on the evaluation of prospects. The appendixes include mineralogical identification tables, a summary of the laws and regulations applying to prospecting in the United States and the British Commonwealth, and information on prices currently being paid for uranium ores and concentrates.

The search for uranium to-day is so intense that, even though it is little more than a year since the text of Nininger's book went to the publishers, the emphasis he gives to the potentialities of vein-type deposits as the future producers of uranium is already out-dated. It is now apparent that, as has been the case with copper and other minerals, large bodies of low-grade ore capable of being worked on a vast scale will provide the bulk of the uranium of future years.

Typographical errors are infrequent and rarely cause confusion, but irregularities such as the use of 'thucholite' as a mineral species, 'columbium' in preference to niobium and the loose usage of 'secondary' (p. 42) might have been avoided. These minor errors fortunately detract little from the usefulness of the book. It is undoubtedly the most comprehensive publication of its kind and is deservedly in world-wide demand.

S. H. U. BOWIE

The Biochemistry of Vitamin B_{12}

A Symposium held at The London School of Hygiene and Tropical Medicine on 19 February 1955. Organized and Edited by R. T. Williams. (Biochemical Society Symposia, No. 13.) Pp. v+123. (Cambridge: At the University Press, 1955.) Paper, 13*s*. 6*d*. net; cloth, 20*s*. net.

AT the meeting in Oxford in 1911 of the newly formed Biochemical Club, now the Biochemical Society, it was proposed to hold meetings for the discussion of special subjects. At the first meeting in December 1914, under the chairmanship of Prof. A. Harden, micro-methods of analysis were demonstrated—truly a prophetic and apt beginning by biochemical pioneers. Further meetings followed at irregular intervals until 1928; after a gap of thirteen years they were resumed, as symposia, in 1941.

In 1948 the Biochemical Society began publishing full reports of these symposia, and now, ably organized and edited by Prof. R. T. Williams, the meetings and their reports are a well-established feature of biochemical progress. A welcome is to be extended to the appearance of the latest volume, the thirteenth of the series, devoted to vitamin B_{12}. Its subject-matter was reviewed earlier in *Nature* (175, 185; 1955) and need not be repeated here.

The symposium was held in February, 1955; barely five months later, an international team of workers, headed by Dr. Dorothy Crowfoot Hodgkin in Oxford and Sir Alexander Todd in Cambridge, announced the complete structural formula of vitamin B_{12} (see *Nature*, 176, 325; 1955). It was a happy thought to print that formula in the volume, the last to be produced by Prof. Williams, who after long service is retiring from the editorship of the symposia. He takes with him the thanks and good wishes of all biochemists.

Compounds with Condensed Thiophene Rings

By Howard B. Hartough and S. L. Meisel. (The Chemistry of Heterocyclic Compounds: a Series of Monographs, Vol. 7.) Pp. xv+515. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1954.) 16.50 dollars.

THIS volume is one of a pair as well as one of a series, for it is the complement of an earlier volume by H. B. Hartough on uncondensed thiophenes. The ramifications of thiophene chemistry and its recent rapid development explain the need for two volumes to accommodate a survey which is at once comprehensive, critical and readable.

The present volume begins with a discussion of orientation in the substitution reactions of furan, thiophene and their benzo-derivatives: this touches on problems which are still incompletely resolved and extend beyond the chemistry of thiophenes. Subsequent chapters contain a systematic account of thianaphthenes, thioindigo, dibenzothiophenes and polycyclic thiophenes, including those in which another fused heterocycle is present; the final chapter describes condensed systems of selenophene and tellurophene. The text, which is clear and well illustrated by structural formulæ, maintains a good balance between descriptions of synthetic methods and chemical properties. Much useful information is assembled in tables inserted in appropriate chapters and serving, with the aid of a general index, to locate a compound in particular quest. An extensive bibliography and a separate list of patents are intended to be complete up to May 15, 1952.

The book will be invaluable for reference purposes, a necessity for all libraries, and a boon to workers in its particular field both now and for many years to come.

The Structural Chemistry of Proteins

By Prof. H. D. Springall. Pp. x+376. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1954.) 45s. net.

FEW satisfactory text-books of protein chemistry have appeared. On one hand, the subject is very extensive, and much of it lies in biochemistry and technology; on the other hand, little structural information is available in all but one or two cases. The present volume concentrates on structural aspects and within its chosen limits is excellent. It provides an adequate account of the organic chemistry, including methods of synthesis of peptides and analytical methods of determining amino-acids and end-groups.

A strong feature of the book, however, is its discussion of physical methods. Students will not find this easy going. The summary of the physical methods of the determination of shape and size is given in such a condensed form that it is probably fair to say that it will only be understood by physicists and physical chemists who have specialized to some extent in the various methods. But readers who are not interested in these technical matters will be able to omit these pages or be content with a general impression.

Used in this way, students will find it a very good introduction to modern studies of proteins, and research workers an excellent monograph to keep on their book-shelves. It is well printed and bound, and quite reasonably priced for the present day.

J. A. V. Butler

The Birds of the British Isles

By Dr. David Armitage Bannerman. Vol. 3: Sylviidae, Turdidae, Prunellidae, Troglodytidae, Cinclidae, Hirundinidae. Pp. viii+399+51 plates. Vol. 4: Apodidae, Caprimulgidae, Meropidae, Upupidae, Coraciidae, Alcedinidae, Picidae, Cuculidae, Strigidae. Pp. xii+260+29 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1954–55.) 45s. net each vol.

WITH these two volumes, Dr. D. A. Bannerman's stately work—with the fine plates by the late George Lodge—has covered at least a third of its ground. Vol. 3 completes the account of the passerine birds with, notably, the warblers, thrushes and swallows. Vol. 4 deals with six of the less numerously represented orders—swifts, nightjars, woodpeckers, cuckoos, owls, and that which includes the bee-eater, hoopoe, roller and kingfisher.

It is an advantage that the author is not tied to any standard length in discussing a species; and so he gives long and scholarly articles on those which present problems of special interest, such as the swift and the cuckoo. Nevertheless, even the accidental vagrants, such as three species of nightjar other than the native one, are by no means cursorily dismissed. The blue-cheeked bee-eater, added to the British list only in June 1951, finds its due place; and it provides occasion for quoting at length General Hutson's description of the migration of this and the European species in Egypt and Asia. Indeed, the unusual amount of evidence based on observations, including the author's own, in other parts of the world is again noteworthy as a particularly valuable feature of the work.

Landsborough Thomson

Australia

A Camera Study. By Frank Hurley. Pp. 208. (Sydney and London: Angus and Robertson, Ltd., 1955.) 45s.

THIS is a book of photographs, some coloured and some in black-and-white, by the distinguished Australian photographer, Frank Hurley. Its purpose is to record some of the scenery in town and country in Australia. It fulfils this modest purpose admirably, and it gives anyone proposing to emigrate to Australia a vivid idea of the continent: its clear skies; its parched red inland country; its monster cities; and its forests, mines and pastures. It is not an easy landscape to photograph, for much of it is monotonous and uneventful; but Mr. Hurley's great skill brings the scenery to life in a remarkable way. One has only to turn its pages to realize what opportunities await the biologist, the geologist and the geographer there, and to renew one's admiration at the way such a tough continent has been tamed in less than two centuries.

The book is well produced (a compliment which is unlikely to have been paid to Australian books fifteen years ago), and the colouring of some of the plates is admirable; only occasionally, in the plate of a Queensland sugar-field, for example, are the values false. In this sort of a book one does not expect a text as elegant as the pictures: Mr. Hurley's photographs are accompanied by accurate but undistinguished comments, in the style of a film travelogue; but it is a book to look at, not to read.

Eric Ashby

Suicide in London

An Ecological Study. By Peter Sainsbury. (Maudsley Monographs, No. 1.) Pp. 116. (London: Chapman and Hall, Ltd., 1955. Published for the Institute of Psychiatry.) 15s. net.

THIS study consists of a report on two separate but related investigations on suicides taking place in the London area in the period before the Second World War. In the first, an attempt is made to correlate the suicide-rates in the twenty-eight metropolitan boroughs during 1929–33, with selected social characteristics found in the "New Survey of London Life and Labour". The second consists of an analysis of 409 suicides reported to the North London Coroner during 1936–38. The data are painstakingly analysed, and correlations are obtained between suicide-rates and certain indexes of social disorganization.

The second part of the study is the more interesting, as an essay in method, and shows that the information available in coroners' records is capable of providing valuable supplementary information on suicides. It would, however, have been interesting to try to compare the London material with that in provincial towns, and possibly country areas, to test whether some of the regularities that are observed in London also hold outside the metropolis.

INTER-UNIVERSITY COUNCIL FOR HIGHER EDUCATION OVERSEAS

IN 1944 the Secretary of State for the Colonies invited British universities to set up an Inter-University Organization to assist the development of higher education in the Colonies. This invitation was accepted by all the universities, and their representatives met in London in the rooms of the Royal Society, on March 8, 1946, to establish themselves as the Inter-University Council for Higher Education in the Colonies. The original title later became inappropriate and was changed to Inter-University Council for Higher Education Overseas; but the objects of the Council remained unchanged, namely, those of assisting the development of universities within British territories which are, or have recently been, Colonies, and within the Sudan. A review of the work of the Council for the period 1946–54 was presented to Parliament last year by the Secretary of State for the Colonies, and this has now been published*.

When the Council was established in 1946, it was concerned with two universities which have since moved outside its sphere—the University of Ceylon and the Hebrew University of Jerusalem. In 1948 Ceylon became a Dominion, while the termination of the Palestine Mandate, also in 1948, removed the Hebrew University of Jerusalem from the interests of the Council. From the start the Council was especially invited to extend its assistance to the Sudan, and more recently it accepted the invitation of the Secretary of State for Commonwealth Relations to assist the development of university education in the Federation of Rhodesia and Nyasaland.

At the close of the Second World War there were only two universities in the British Colonial territories and the Sudan apart from those in Ceylon and Palestine. These were the Royal University of Malta and the University of Hong Kong, both of which had suffered much damage as the result of the War. At the present time there are three universities—Malta, Hong Kong and Malaya—and six university colleges—the University College of the West Indies, the University College of the Gold Coast, University College, Ibadan, Nigeria, Makerere College (the University College of East Africa), the University College of Khartoum, and the recently established University College of Rhodesia and Nyasaland. Some of the foundations which existed in 1946 now fall within the province of a post-war development parallel to that of the university institutions, namely, the provision of higher technical education in the Colonies under the guidance of the Advisory Committee on Colonial Colleges of Arts, Science and Technology, a body analogous to the Inter-University Council for Higher Education Overseas. Institutions which come under the Advisory Committee on Colonial Colleges of Arts, Science and Technology include Fourah Bay College, Sierra Leone, Kumasi College of Arts, Science and Technology, Gold Coast, College of Technology, Nigeria, and the inter-Territorial Royal Technical College, Nairobi.

The specific task of the Inter-University Council for Higher Education Overseas has been to assist the three universities and the six university colleges, and this report shows how well the purpose has been achieved. Although figures alone can be dry and unrevealing, the total number of students attending the university institutions coming within the province of the Council illustrates one aspect of the effectiveness of its work. In 1946 the total number of students attending such institutions, of which there were only four active at that time, was 726. In 1949, by which time eight of the institutions were effectively working, the total was 2,456, while in 1954 it had risen to 4,592. As was to be expected, in 1955 the figure approached 5,000. In addition, during the same period, the number of overseas students in universities of the United Kingdom and Ireland grew from 2,014 in 1946–47 to 9,901 in 1954–55.

All the universities and colleges are inter-racial. None has a quota system for races, although preference is given to local candidates. They are wholly or mainly residential, both for students and staff.

Two important principles which the Council has followed during its nine years of existence have been, first, that there should be no compromise on the matter of standards of teaching and of academic attainment, and second, that the university institutions with which it is concerned should be completely autonomous. A price that had to be paid for the achievement of attaining the academic standards of a first-class university has been that initially the number of students was small, with a high ratio of staff to students. This in turn has meant that the institutions required very large funds, both capital and recurrent. It follows that only a few of these university institutions could be established at any one time. There is no doubt that this policy has justified itself, since the Colonial university institutions are fully accepted within the university world. This has been greatly assisted by the fact that all the university colleges have entered into special relationship with the University of London. This has meant that the degrees the students take are those of the University of London. Furthermore, the University of London interests itself in appointments to the academic staff, particularly in the Faculty of Medicine. The Colonial university institutions are already beginning to attract research workers from outside, and they and their graduates are undoubtedly building up a reputation in the world at large for the territories they represent.

The maintenance of the autonomy of the university institutions has been important both with respect to finance and constitution and has been adequately safeguarded in every instance. The independence of the university institutions has meant that the relationship of the Inter-University Council to them has been advisory only.

The three universities, Malta, Hong Kong and Malaya, award their own degrees. The six university colleges will ultimately award their own degrees; but meanwhile their students pursue courses leading to the degree examinations of the University of London. The University of London alone among British universities awards degrees to external students. Special relationship with the University of London is a temporary arrangement intended to safeguard the academical standards of the university colleges while they are establishing their reputations and building up their experience. The first of the colleges to assume university status will be the University College of Khartoum, which has announced its decision to seek degree-granting authority in the present academical year. There is no uniform scheme for special relationship with the University of London and it is developed separately for each college, the college working out in consultation with the University of London the arrangements which best suit its particular local conditions. For example, if the development of secondary schools in a particular territory makes desirable that a minimum entrance requirement to the university college should be adopted which is lower than that obtaining in the United Kingdom, the college and the University of London can agree to accept a modified standard of admission. If a lower standard of entrance examination is instituted, the length of the degree course is normally extended by one academical year. Special relationship involves the arrangement that members of the staffs of the university college take part in the setting and marking of the examinations for their own students, with examiners from the University of London. Furthermore, full-time members of the teaching and research staffs of the colleges in special relationship with the University of London may, if appropriately qualified, register as internal students for the London Ph.D. degree, and continue to carry out their research work in the university college.

---

* Inter-University Council for Higher Education Overseas, 1946–1954 (Cmd 9515.) Pp. iv+41+4 plates. (London: H.M. Stationery Office, 1955.) 2s. 6d. net.

The Inter-University Council itself meets four times in each academical year, and annually appoints an executive committee which usually meets monthly during each session. Each of the universities in the United Kingdom, together with the three Colonial universities, appoints a representative member. Recently university colleges in England have also appointed representatives, while the Council has co-opted additional members in their individual capacities. The educational advisor to the Secretary of State for the Colonies, Sir Christopher Cox, has served *ex officio*. The late Sir James Irvine was the first chairman of the Council and served until February 1951, when he was followed as chairman by Sir Alexander Carr-Saunders, who had until then been vice-chairman. Sir Raymond Priestley then succeeded Sir Alexander as vice-chairman. The secretary has until recently been Dr. Walter Adams, who left in May 1955 to succeed Dr. W. Rollo as principal of the University College of Rhodesia and Nyasaland. He was succeeded in the office of secretary by S. J. Worsley. By overlapping membership and by other means, the Council has maintained close co-operation with the Advisory Committee on the Colonial Colleges of Arts, Science and Technology, with the Advisory Committee on Education in the Colonies, with the Colonial Research Council and with the various advisory research councils and committees of the Colonial Office. It has worked in very close association with the University of London Senate Committee on Colleges Overseas in Special Relationship. The Council is represented by two members of the Colonial University Grants Advisory Committee. The cost of the Council's secretariat, office accommodation, visits and advertising of vacancies has been met by an annual grant from the Colonial Office.

The Council has attached great importance to the visits which its members and other representatives have been enabled to make to the overseas universities and colleges, and indeed its work would not have been possible without them. Air transport, which has developed so much since the War, has made possible the close personal contacts between the overseas and the home universities, the visits of experts and examiners, the frequent leave of academic staff, and the rapid exchange of correspondence and examination papers. The post-war period has also fortunately coincided with economic prosperity in almost all the overseas territories, and with the growth of responsible nationalism and the acceptance by both Great Britain and the dependent territories of a policy of transference of power to which the development of universities is well attuned. The University Grants Committee in the United Kingdom has said that "the dependence of the Universities on the State is balanced by a dependence of the State on the Universities". This mutual dependence and partnership is as clear in the Colonies as it is at home. The prestige of university institutions as a whole has never been higher, and they are exceptionally responsible to their national and international obligations.

In the future, as in the past, the overseas universities and colleges will look for co-operation to the universities of the United Kingdom. Although the University of London has been enabled, by its special position, to give more help than other universities in Britain, one may hope that the other universities will not fail to take as much interest in the overseas institutions as circumstances will make possible. One way in which they can help is by assisting the promising graduates of the Colonial university institutions to come to Great Britain for postgraduate and further specialist studies. The need for finances for the provision of postgraduate fellowships is clear. It is to be hoped that all will help who wish to see the development of universities in the British Commonwealth go forward in a manner which is worthy of the name which the Commonwealth has itself won in world affairs.

F. G. YOUNG

ZOONOSES IN EAST AFRICA

THE annual scientific conference organized by the East African Medical Research Scientific Advisory Committee was held in the Makerere College Medical School, Kampala, Uganda, during January 11–13. Some eighty delegates came from East African territories, and visitors from Britain, Egypt, Israel and South Africa joined in the discussions. In opening the conference, the Governor of Uganda spoke of the dependence of East Africa upon Great Britain and the United States of America for basic long-term research and on support for such research, and this was well illustrated in many of the discussions, particularly in relation to taxonomic research.

Dr. H. Hoogstraal, of the U.S. Naval Medical Research Unit, Cairo, described the great faunal explorations which the Unit has carried out in north-eastern Africa as a basic preliminary to ecological studies. This immense collection of mammals, birds, reptiles, amphibians and ectoparasites is now undergoing detailed examination, and much new information is emerging and will be made available in keys and check lists. Much admiration was expressed by conference members of this study; it is not being carried out under the pressure of a disease outbreak, in which circumstances hasty and inaccurate conceptions can arise; and it is regrettable that in East Africa so little collecting is being done. The need for a basic faunal study unit is great, there are serious gaps in existing collections and many taxonomic concepts require stabilizing. It is difficult to get bird, mammal or insect identifications done in East Africa, and the resources of the British Museum are frequently called upon. But there are limits to these resources and frequent delays in identifications, despite the willing help of the Museum staff, who have many other calls upon their services.

The difficulties and expensiveness of faunal research studies in East Africa were clearly recognized, and Dr. Hoogstraal stoutly maintained that the situation is not so gloomy as some have pictured. The British are notable collectors and senders-home of material, the British Museum's resources are immense and can be supplemented and more and better keys can be provided.

Nevertheless, the lack of basic East African data makes research upon the local zoonoses difficult, as was shown in symposia on rabies, *Q* fever, brucellosis, helminthiasis, virus zoonoses and trypanosomiasis. The status of trypanosomiasis as a zoonosis is not at present established, and the conference heard of new efforts being made in the crucial experiment of isolating *Trypanosoma rhodesiense* from wild animals. Dr. K. C. Willett spoke of several lines of investigation which suggest the possibility that *Tr. rhodesiense* may have developed from *Tr. brucei*, the game trypanosome which is non-infective for humans, by repeated passages through *Glossina pallipedes*, and this possibility is being investigated. The conference warmly welcomed the presence of Dr. B. Weitz, of the Lister Institute, whose studies of the blood meals of tsetse fly and other arthropods are so important to East Africa. If the hosts of tsetse fly could be clearly identified, specific measures of eradication could be devised and the distasteful method of wholesale game slaughter discontinued. Thus Dr. Weitz mentioned that he has never found the blood of certain common game animals in tsetse fly. The policy of wholesale game slaughter found no support in the conference, and this for two reasons. First, because of the promises held out by further work on the lines Dr. Weitz had indicated, which would, it was hoped, advance rapidly; and secondly, because of the general realization that until population pressure rises to the point where there is a real need for the land now occupied by tsetse, there is not likely to be any major decrease in the size of such areas. There is, therefore, no point in adopting such an unpleasant and unnecessary policy in East Africa.

Dr. R. B. Heisch pleaded for a holistic synecological approach to the problem of East African zoonoses, on a basis of detailed taxonomic studies and investigations of the host–parasite relationships. This approach has been utilized in existing studies of plague, relapsing fever and kala azar in East Africa. Dr. Heisch believes that the more resistant animal hosts may be important in maintaining the disease organisms, though this is scarcely the case in the virus zoonoses, where a continuous supply of non-immunes, who circulate the virus in the blood in large amounts, is an essential to maintaining a zoonosis. Moreover, when a zoonosis gets under way, man-to-man contact may be sufficient to keep the infection spreading, and in Kenya the kala azar epidemic may be spreading in this way. But Dr. Heisch's conception is worthy of serious study; man's fellow sufferers are too often regarded as his enemies. The snail, that humble but useful member of the aquatic community, as Mr. R. Beauchamp called it, is the chief sufferer from schistosomiasis. The resistant animal hosts of a zoonosis must not be too readily dismissed.

Much more information is needed, too, about the small mammals of East Africa, which may be involved in a number of zoonoses, and co-operation is most desirable between those who trap mammals for a variety of purposes. As much serum as possible should be collected, and a plea was made for the setting up of a 'museum' of deep-frozen sera from mammals, as this would greatly expedite the serological investigations of zoonoses. Detailed synecological studies might explain some of the discontinuities in disease incidence in East Africa which cannot at present be explained. Thus rift-valley fever antibodies are present in sera of cattle in both the Eastern and Western Rift valleys, though they are not found in sera from the higher intervening areas in Uganda. Knowledge is too scanty at present to explain these discontinuities, but in this connexion much attention is being paid to birds as possible disease vectors. Dr. R. M. Taylor described the major part they are believed to play in the endemiology and epidemiology of West Nile virus infections in Egypt and in Israel. The breeding seasons can provide a fresh stock of non-immunes, and in their breeding areas some virus infections may be endemic. In the areas to which or through which, such birds migrate, epizootics and outbreaks of zoonotic diseases may occur. Unusual climatic conditions may delay, alter or extend these areas, leading to mysterious outbreaks of disease in areas previously unaffected or only affected at long intervals. These possibilities in relation to a number of virus zoonoses are now being investigated, and they may be of importance in such an epizootic disease as African horse sickness. There are periodic outbreaks of this disease in widely separate geographical areas after intervals of freedom, which may extend to ten or twelve years.

But in searching for explanations of these and other zoonotic outbreaks, there are limitations in the taxonomic approach which should be borne in mind. Thus Dr. A. Haddow pointed out that the fact that the same species exists in two different areas is no guarantee that it behaves identically in both places. In one place *Aedes simpsoni* will bite man freely, whereas as little as ten miles away it will only bite animals. Some anopheline species feed exclusively by day in some areas, exclusively by night in other areas. There is, in a sense, no end to these studies. Moreover, a parasite introduced into a new area may adapt itself to previously resistant local vectors. Dr. M. Davies quoted examples of this from Israel in relation to schistosomiasis, introduced by immigrants from Iraq, and filariasis introduced from Cochin. Therefore, on a basis of sound taxonomy, each zoonosis requires specific ecological study in each affected area. Lack of appreciation of this has led to much wasted effort in trying to apply control measures, devised upon a basis of experience elsewhere, to a specifically local problem. Thus in Kenya, night screening of cattle from mosquitoes protects them from Rift Valley fever, whereas in South Africa the vectors are day-biting mosquitoes.

If each local problem requires specific study, then it is important to start in the most promising areas. In East Africa, the forest fringes are such areas. There the species of the forest and the open country come in contact, and there are other species which can only maintain themselves on the forest fringes. But this is only one such 'fringe area'; in Kenya, kala azar is somehow connected with the termite hills which represent another such contact area. Several speakers stressed our ignorance of forest animal ecology and hoped that more work would be done in this field. Others directed attention to the effect of turning pasture land into arable land, and to the effects of new irrigation schemes in East Africa.

One curious feature of the conference was the repeated criticism of the laws of the East African territories. It was pointed out that existing legislation in many fields is extremely advanced and ridiculously at variance with existing practice. The laws cannot, in fact, be enforced, and this has had unfortunate results. In other fields they are curiously restrictive, as was brought out by reference to campaigns against rabies. There is no legislation against laying poison bait, but the officers who lay it are personally financially responsible for any ensuing claim for damages. So much publicity is therefore necessary before laying bait "that even the jackals heard about it", and such campaigns have been extremely ineffective.

The conference revealed the enormous fields for research that the zoonoses hold in East Africa, and in his closing remarks the president, Mr. H. R. Binns, of the East African Veterinary Research Organization, stressed this. He called for the closest cooperation of medical and veterinary research workers and other scientists which has been so fruitful in the past, and emphasized the willingness of all institutions and organizations in East Africa to welcome visiting workers from other countries who wish to help in the solution of East Africa's many problems.

J. N. P. Davies

OBITUARIES

Prof. A. O. Rankine, O.B.E., F.R.S.

The death, on January 20, of Alexander Oliver Rankine at the age of seventy-four removes a much respected figure from scientific circles in London, especially those connected with applied physics. He played a leading part in the development of important branches of that subject, including optics and geophysics, not only in their technical aspects but also in connexion with the relevant organizations, both academic and professional. In later years he gave much devoted service to the Royal Institution. He was a frequent lecturer there, and was honorary secretary during 1945–52.

Born in 1881, he was the son of the Rev. John Rankine, of Guildford, a Baptist minister, and started his education at the Board school at the age of four years. Later on, he attended Guildford Grammar School, whence he won a county major scholarship to University College, London, and graduated with first-class honours in physics in 1904. He was awarded the D.Sc. degree in 1910 for his published work, mostly on the viscosity of gases and associated studies of the dimensions of gaseous molecules.

He held a research appointment in University College during 1904–19, except for a period in the Admiralty Experimental Station, Harwich, during 1917–18, in which he worked on a method of telephonic communication by the modulation of a beam of light. He was made O.B.E. in 1919. After the First World War he accepted the post of assistant-professor of physics in the Imperial College of Science and Technology, South Kensington, being later promoted to a full professorship. His outstanding personal gifts, generosity and organizing capacity brought him into prominence, and when Prof. F. J. Cheshire (director of the Technical Optics Department) retired in 1925, Rankine was appointed to that post, which he held until 1931, when the Optics Department became a postgraduate branch of the Physics Department under Prof. (now Sir George) Thomson. About this time he became the last president of the Optical Society.

The great interest in optical research stimulated by the First World War had diminished, and the Optical Society lacked the resources to maintain it as an independent body. Under Rankine's guidance it was united with the Physical Society. (Perhaps the wisdom of this step was not fully apparent until some years later, when the Optical Group of the Physical Society was formed with his help and has continued increasingly to flourish.) Rankine was president of the Physical Society for the first two years after the union. He had always taken a keen interest in that Society as its honorary secretary (1923–29) and member of Council.

He was one of the founder fellows of the Institute of Physics and served on the Board in various offices, including that of honorary secretary and vice-president during 1923–37; also during 1943–47. His tolerance and level-headed counsel made him a highly valued member of committees, and a large amount of such work fell to his share, including various tasks in connexion with Section A of the British Association, of which he was president in 1932.

In the early nineteen-thirties, Rankine became interested in the rapidly developing subject of geophysics, and gave much help to the early development of related studies in the Imperial College. Various papers under his name on geophysical instruments were beginning to appear at the time of his election to fellowship of the Royal Society in 1934. He left the Imperial College in 1937 to become the chief physicist to the Anglo-Iranian Oil Company, in which capacity he paid several visits to Persia, encountering various adventures which he would describe in his own amusing way. Between 1942 and 1945 he was seconded to the Petroleum Warfare Department, in which connexion he had much to do with the development of 'Fido'—the use for fog-dispersal of petroleum vapour burners flanking landing strips on air-fields. A visitor to Earl's Court on a wintry day might find Rankine and his assistants wrapped in duffle-coats and working cheerfully in icy cavernous gloom with giant fans, rows of burners on the floor, and arrays of electrical thermometers to record the three-dimensional temperature distribution. It was a task for which his earlier researches on the viscosity of air had prepared him very well.

After service as visitor and manager, he was appointed in 1945 honorary secretary of the Royal Institution, a post which was to involve him, a few years later, in acutely controversial personal issues. Few will be disposed to deny the courage and tenacity with which he successfully maintained his position and views in the face of increasing difficulties and deteriorating health. The key to his general position on social issues lay in his early upbringing, and an instinct to support humbler ones against power and privilege. He had, as he said, a natural sympathy with the rebel, though he took his place easily and naturally in any *milieu*. His rare gift of friendship will make his loss widely mourned.

He married, in 1907, Ruby Irene, daughter of the late Mr. Samuel Short, of Reading, and had two sons and two daughters. L. C. Martin

Dr. A. L. Hall, F.R.S.

Arthur Lewis Hall, one of the foremost contributors to South African geology, died on August 13, 1955, at his home in Pretoria.

Hall was born on January 10, 1872, at Birmingham. A scholar of Gonville and Caius College and Harkness Scholar in geology at Cambridge, where later he also took his doctorate, he was appointed field geologist to the Geological Survey of the Transvaal in 1903. In 1915 he became assistant director of the Geological Survey of the Union of South Africa and in January 1932, on reaching the age limit, he retired from official duties after thirty years of devoted service to the State and to South African geology. He then busied himself as a consulting geologist, until his eyes began to trouble him and he was forced to withdraw from further active work in the profession in which he took such a lively interest and achieved so much.

Apart from general features, little was known of the geology of the Transvaal in 1903. Consequently, almost wherever his work led him, Hall found himself breaking fresh ground, and he can justly be counted among the able pioneers of South African geology. Most of his work was done in the eastern and north-eastern Transvaal in a much diversified country of rugged mountains and low-lying bush-veld. In the early days, field-work there was accompanied by many obstacles as well as a vast amount of fatiguing work that called for ingenuity, courage and the ability to overcome difficulties in order to achieve success. Hall, a great enthusiast and an energetic worker, possessed these qualities to a marked degree. His strong constitution and tenacity of purpose enabled him to produce the fine geological maps for which he is noted.

By his strenuous field-work, his detailed microscopical studies of large amounts of petrological material and other research work, Hall was able to make many important contributions to geology in the fields of pure as well as applied science, and thus exerted a lasting influence on geological development over a wide part of the Transvaal. He will be especially remembered for the leading part he played in the delineation of the Transvaal System and its relationships to other formations, his studies of the Archæan formations, his investigations of the country's mineral resources and, above all, his elucidation of that great igneous assemblage known as the Bushveld Igneous Complex, with its wide, contact metamorphic aureole. He conducted the Shaler Memorial Expedition and also the Bushveld excursion of the International Geological Congress through the northern and eastern parts of the Complex, when he was able to present "much important field-evidence to a phalanx of geologists that included the élite of international petrographical thought".

International geology was advanced by Hall's share in the deliberations during the sessions of the International Geological Congress held in Spain, the United States and Russia. The success of the Congress in South Africa in 1929, of which he was the secretary-general, was largely due to his organizing abilities.

The Geological Museum of the Geological Survey owes a very large part of its utility and attractiveness to his energy and care.

Hall was a past-president of the Geological Society of South Africa, a Fellow of the Royal Society of South Africa and of the Geological Society of London, a council member and president of the South African Geographical Society, a corresponding member of the Geological Society of America, and a regional vice-president of the Society of Economic Geologists, United States of America. His distinguished services to geology were recognized by his election as a Fellow of the Royal Society and as an honorary member of the Geological Society of South Africa, and in the award to him by the Geological Society of London of the Murchison Medal, and by the Geological Society of South Africa of the Draper Medal.

Socially, Hall was a man of distinct personality whose sterling worth and ability aroused the deepest respect and admiration among those who worked with him. He will be remembered as much for his intense humanity as for his geological prowess.

Louis T. Nel

Dr. E. C. S. Megaw, M.B.E.

By the sudden death of Dr. E. C. S. Megaw on January 25 at the early age of forty-eight, the nation has lost one of its most prominent scientists in the field of applied radio-physics.

Eric Christopher Stanley Megaw, the eldest son of a Belfast solicitor, was educated at Campbell College and The Queen's University, Belfast; and, after obtaining his B.Sc. degree in electrical engineering, he was elected to a research fellowship at the Imperial College of Science and Technology, University of London. While still a schoolboy, he became prominent among radio amateurs, and was reputed to be the first amateur in Ireland to receive signals from New Zealand on his home-made apparatus.

It was at the Imperial College that his scientific interest in the generation and use of very short radio waves was aroused; and, under the direction of Prof. C. L. Fortescue, he studied electronic oscillations in valves. He joined the staff of the Research Laboratories of the General Electric Co., Ltd., in 1930, and rapidly acquired a reputation as a result of his research on the magnetron short-wave oscillator. A paper on this subject read before the Radio Section of the Institution of Electrical Engineers in 1933 was awarded the Duddell Premium of the Institution. He also received the diploma of the Imperial College and later the D.Sc. degree of Belfast.

In the early days of the Second World War, Megaw, as a member of the staff of the General Electric Company, was, with his colleagues, working on behalf of the Admiralty and was closely associated with the design and development for production of the cavity magnetron, experimental models of which had been produced by Prof. J. T. Randall and Dr. H. A. H. Boot, working at the University of Birmingham. As is well known, the cavity magnetron was widely used on both sides of the Atlantic and it has been described as the biggest single inventive contribution towards the technical superiority which the Allies achieved over their enemies. Later in the War he began to investigate the propagation characteristics of radio waves on wave-lengths from a few metres to 3 cm. over both land and sea; and his active interest in this field of research continued up to the time of his death.

Dr. Megaw was appointed M.B.E. in 1943, and three years later he accepted the post of superintending scientist of the Radar Branch of the Admiralty Signal Establishment. Later he was appointed director of physical research in the Royal Naval Scientific Service; and although this involved him in an increasing amount of administrative work, his active interest in the scientific side of radio research remained.

He was the pioneer investigator in Britain who in 1950 directed attention to the propagation characteristics of very short radio waves by scattering in the troposphere, and the advantages, which are only now being realized, of the use of scattering technique in certain fields of communication. His theoretical and experimental work on this problem were assisted by reviewing the analogous case of the fluctuations of light waves transmitted through a turbulent atmosphere; and he used the subject of "Waves and Fluctuations" in his chairman's address to the Radio Section of the Institution of Electrical Engineers in October 1952.

For several years past, Megaw was an Admiralty representative on the Radio Research Board of the Department of Scientific and Industrial Research, and a member of its Tropospheric Wave Propagation Committee. His expert advice and assistance on these bodies will be greatly missed. But his reputation was by no means limited to Great Britain. He attended several General Assemblies of the International Scientific Radio Union in various European countries; and at these he made important contributions to the sessions concerned with tropospheric wave propagation. On such visits, as on all other occasions, he was a delightful companion with an enviable command of the local language, and a flair for knowing the best, inexpensive places for good food and wine. His interest in art, architecture and stained glass were also evident by the opportunities he seized when visiting foreign capitals. He is survived by his wife and two sons. R. L. Smith-Rose

---

Dr. Megaw's outstanding ability was recognized in the Royal Naval Scientific Service by his promotion in one step from senior principal scientific officer to chief scientific officer, and his appointment as director of physical research in 1950. Although his previous researches had been mostly in radio, he soon showed that his skill was in no way limited to that field. He brought a freshness of outlook and keen understanding to a wide variety of problems, and his extraordinary energy enabled him not only to direct a formidable programme of research and development but also to initiate and play a direct part in one of its most successful projects. Although security considerations prevent any detailed account of this work being given at the present time, his place in the records of naval science is already assured.

Megaw was not only gifted as a scientist. He possessed personal qualities which contributed no less to the successful outcome of his endeavours. His integrity, sincerity, loyalty and friendliness, combined with a high sense of duty, made him an ideal leader. No one who had the fortune to work with him could have failed to gain inspiration and encouragement from his example.

Megaw will be sadly missed. The loss to naval science will be particularly felt at a time when men of his kind are so scarce. My own association with him was of the happiest, and I could not have wished for a truer friend or more loyal colleague.

H. F. Willis

Mr. D. J. Matthews

With the death at nearly eighty-three years of age of Donald John Matthews, the science of oceanography has suffered the loss of a man of very distinguished standing. He was born at Surbiton in July 1873, was educated at Marlborough and University College, London, and died recently at Camberley. His long life was filled with an astonishing variety of professional activities, and was marked by great skill with wireless, photography and microscopy as hobbies. It was in 1902 that he first took up oceanography when he entered the service of the Marine Biological Association of the United Kingdom, after having been for some years an analytical chemist and research chemist with the British Aluminium Company.

In his University College days, Matthews worked under Sir William Ramsay at the exciting time when the inert gases were being isolated. Letters exist in which Ramsay gives great credit to Matthews for working up the minerals which proved eventually to contain helium, refers to him as a most capable manipulator, and remarks upon his love of studying minute marine animals under the microscope. While at Plymouth, Matthews published some notable papers on the oceanography of the waters off the south-west of the British Isles. In 1913 he was engaged aboard S.S. *Scotia* on studies of the waters around Newfoundland to provide information upon which could be based action designed to lessen shipping risks in those waters. The cause was the *Titanic* disaster and the outcome the International Ice Patrol. After a short time spent working at Rothamsted Experimental Station around 1920, Matthews entered the Scientific Service of the Admiralty in the rank of principal scientific assistant, and was, until 1936, seconded to the Hydrographer of the Navy. It was as occupant of that post that most people will remember him, and it was during that service that he published his well-known "Tables of the Velocity of Sound in Pure and Sea Water for use in Echo Sounding and Sound Ranging". These tables have been an invaluable tool in many hands, and will doubtless be the chief monument of the kindly, quiet personality who was held in great esteem in oceanographical circles far beyond the bounds of his own country. Matthews, who was a widower, is survived by a son and three sisters.

J. N. Carruthers

NEWS and VIEWS

Physics at Newcastle upon Tyne:

Prof. S. K. Runcorn

DR. S. K. RUNCORN has been appointed professor of physics in King's College, Newcastle (University of Durham). He was educated at King George V School, Southport, and entered Gonville and Caius College, Cambridge, in 1941. He took the Mechanical Sciences Tripos in 1943 and later was awarded the John Winbolt Prize in engineering. During 1943–46 he worked in the Radar Research and Development Establishment of the Ministry of Supply at Malvern, particularly in the field of servomechanisms. He was then appointed assistant lecturer in physics in the University of Manchester and became lecturer in 1948. There, with several younger colleagues, he was mainly concerned with the first systematic study of the variation of the geomagnetic field below the Earth's surface. This work was carried out in coal mines down to a depth of 4,000 ft. His results show that the field increased downwards in a way which was in agreement with the hypothesis that the origin of the Earth's field lies in the deep interior of the Earth: thus excluding the 'bulk' theory initiated by Schuster and H. A. Wilson and recently further discussed by Blackett. In 1948 he was elected a Fellow of Gonville and Caius College and in 1949 became assistant director of research in the Department of Geodesy and Geophysics, University of Cambridge. Together with a group of colleagues he has been very active in the field of rock magnetism, studying both igneous and sedimentary rocks. This work has resulted in new evidence for reversals of the geomagnetic field and for polar wandering. To test the latter hypothesis, he has collected rocks in the United States of America. He has also made both observational and theoretical contributions to the understanding of the secular variation of the Earth's magnetic field and the origin of the Earth's general field. Under his stimulation a group of physicists has made important contributions to various aspects of the physical problems involved in this study: thus Dr. Hide has made some very interesting experimental investigations of the effect of rotation on convective systems. The results are of great interest, particularly in relation to meteorology. Other such work has been concerned with the electric conductivity and temperature of the Earth's mantle. Dr. Runcorn spent the summers of 1952 and 1953 as a research geophysicist in the University of California at Los Angeles.

Metallurgy at University College, Swansea:

Prof. A. R. E. Singer

As announced some time ago, the Steel Company of Wales and Messrs. Richard Thomas and Baldwins, Ltd., have together made a gift totalling £100,000 for developments in metallurgy at University College, Swansea. It is intended that these developments shall provide special facilities for the scientific study of casting, deformation, welding and other fabrication processes. This extension involves a type of physical metallurgy which can be called 'fabrication metallurgy', and it will be a special line of research and teaching within the existing Department of Metallurgy; the work will be directed by an additional professor.

Dr. A. R. E. Singer, senior lecturer and acting head of the Department of Industrial Metallurgy of the University of Birmingham, has been appointed to the newly created chair. Dr. Singer graduated with first-class honours at the University of Birmingham in 1938, and took his Ph.D. degree in 1946. During 1938–43 he worked in the Metals Division of Imperial Chemical Industries, Ltd., and was at first concerned with research and development in copper and brass, and then in the manufacture of aluminium alloy castings and wrought products. Until 1944 he was development engineer with Birmetals, Ltd., and engaged in establishing methods for the large-scale manufacture of wrought magnesium products, after which he returned to the University of Birmingham as head of a research team examining the welding of aluminium alloys. In 1946 he was appointed to the teaching staff and became responsible for designing, equipping and eventually managing the new Aitchison Laboratories. He is particularly interested in the principles of technical control in metallurgical manufacture and published a paper on this subject in the *Journal of the Institute of Metals* in 1953. His research publications have included work on the cracking of aluminium-base alloys, and special features concerning the plastic deformation of metals.

Birmingham College of Technology:

Mr. James Wilson

MR. JAMES WILSON is leaving the Birmingham College of Technology, where he has been principal for the past ten years, for the post of director of education and training of the British Motor Corporation. He went to Birmingham by way of the University of Glasgow and Coventry Technical College, and during his time at Birmingham he has seen the development of all the departments of the College cope with the greatly increased demands of this great industrial area. In addition to the problems of increasing numbers in higher level courses, provision has been made in a variety of subjects for special and postgraduate courses, an example of work of great and immediate value to people already in industry. Provision has also been made for 'sandwich courses', and there is a substantial and growing amount of research in most of the departments of the College. There has also been notable growth of studies in industrial administration. In the past few years the Birmingham Education Authority has been developing a very large extensions scheme which involves the Colleges of Technology, Art and Commerce, and it is certain that Mr. Wilson and his colleagues will have found their greater material facilities both an inspiration and the occasion for a great deal of planning. Last November H.M. the Queen and the Duke of Edinburgh inaugurated the new buildings and inspected those parts of the new buildings already finished. The College of Technology obtains considerable increased accommodation in these parts, and when the whole provision is available, Birmingham will possess one of the largest technological institutions in Britain. Mr. Wilson's new post is a sign of the times; but though technological education in his College will be well aware of its loss, it is nevertheless the case that such work as he is to do within industry will greatly help to make the best use of the education and training acquired in the technical colleges.

Dr. P. F. R. Venables

DR. P. F. R. VENABLES, who succeeds Mr. Wilson at Birmingham, went from Southend to the Royal Technical College, Salford, in 1947, and since then has contributed very greatly to the development of technical education not only in Salford but also in the north-western region and nationally. The Salford College has always been an important institution in the region, but during Dr. Venables's term of office it has grown in its service and influence. All its departments have increased their facilities to students, both full- and part-time, and in particular the 'sandwich system' has been established; it now has some 430 students, and this number is expected to grow to 1,100 in five years time. This system, in which students alternate periods in the College with periods in industry, shows that Dr. Venables has the full confidence of industrialists in the area, and it may be expected that this work will be an important contribution to the improvement of technological services in the region. But Dr. Venables's work has not been limited to his own area. In 1951 he visited the United States under the Fulbright Scheme to study the work of universities and technical colleges linked with industry, and to see schemes for industrially sponsored research. Since 1954 he has been chairman of the Regional Academic Board, which includes university, technical college and industrial members, and he is also a member of the National Advisory Council for Education in Industry and Commerce. He has also held high office in the Association of Technical Institutions and in the Association of Principals of Technical Institutions. He has recently published an authoritative book, "Technical Education" (see *Nature*, Feb. 18, p. 296), and holds a Leverhulme Research Fellowship to study "Education and Training Schemes in certain industries with special reference to the work of technical colleges and the needs of smaller firms". He was vice-chairman of the national committee which produced the report on "Liberal Studies in a Technical Age". He is leaving Salford after having devised and started an extension scheme expected to cost £1,500,000. He will be greatly missed in the region on account of his knowledge, energy and good fellowship.

Edward Goodrich Acheson (1856–1931)

Edward Goodrich Acheson was born on March 9, 1856, at Washington, Pa. Of Scottish and English ancestry, he died in 1931, and during his life was granted patents for seventy inventions. Outstanding were an industrial method of producing silicon carbide electrothermally (1891), the manufacture of graphite from a coke base in the electric furnace (1893) and the manufacture of pure graphite of high crystallinity (1896 and 1900). Having prepared pure graphite in the electric furnace, Acheson turned his attention to means of disintegrating it and preparing colloidal dispersions. He succeeded in this (1906–7) and made available stabilized dispersions of graphite for lubrication. Colloidal graphite is used to-day to aid the lubrication of mechanical equipment of all kinds, in filament wire drawing and for the production of electrically conducting coatings. At the 150th anniversary of the signing of the Declaration of Independence in 1926, the United States Post Office exhibited seventeen patents of E. G. Acheson which had benefited industry. The Smithsonian Institution has a permanent Edward Goodrich Acheson Exhibit, showing products springing from his inventions and the medals awarded to him. He was awarded the Rumford Medal of the American Academy of Arts and Sciences (1908), the Perkin Medal of the American Section of the Society of Chemical Industry (1910), and the University of Pittsburgh conferred on him the honorary degree of doctor of science in 1909. The present annual world production of silicon carbide for machining and grinding runs into many thousands of tons, with plants in more than twenty countries. Electric furnace graphite in electrode and powder form, made by Acheson's process, is produced in very large quantities, in Britain, the United States, France and other countries. It was this pure form of graphite that was used as moderator in the first nuclear reactor in the world to be built, at Chicago. At one time Acheson was an assistant to Thomas Edison at Menlo Park and carried out development work on early incandescent lamps, while he installed the first electric lighting system in Europe, at Milan. He lived for some time in London.

Recent Solar Activity

Two streams of large sunspots, in latitudes 20° N. and 20° S., were visible on the Sun's disk during February. The total area of sunspots on February 20 was greater than that of any day since 1947, the previous sunspot maximum year. The most recent sunspot minimum occurred during the first half of 1954. Since that time sunspot activity has, with the usual variations, increased steadily, and about twenty-five sunspot groups have exceeded in area 500 millionths of the Sun's hemisphere within the past fourteen months. The mean daily sunspot number for the months November 1955–February 1956 has been around 90. The steepness of the rise in the sunspot cycle is believed to indicate the 'height' of the coming maximum, so that if sunspot activity continues to increase, mean daily sunspot numbers in excess of 150 may be expected by the end of 1956. The actual epoch of sunspot maximum would probably occur during the first half of 1957.

On February 23 at 0330 hours U.T., a large flare was observed on the Sun from an Indian observatory; it lasted until 0510 h. Complete Dellinger-type 'fade-outs' of radio circuits from Hong Kong and Singapore occurred between 0345 h. and 0500 h., such as are normally associated with the ultra-violet light from a large flare. A large increase of cosmic-ray flux was simultaneously recorded by many types of recorders in different parts of the world. A sea-level meson recorder in Great Britain showed a 100 per cent increase in counting-rate starting during the ten-minute period 0340–0350 h. Previous increases associated with solar flares on similar instruments have only rarely occurred and have never exceeded 40 per cent. The flux gradually diminished and normal counting-rate was resumed two to three hours later. Lower-energy cosmic radiation probably continued to arrive from the Sun.

Research in Industry and Government

In the third E. F. Armstrong Memorial Lecture to the Royal Society of Arts, given on November 23, Dr. B. K. Blount, deputy secretary of the Department of Scientific and Industrial Research, reviewed the growth of research in industry in Great Britain, describing the general form of the organization it had taken, and discussed some of the implications. Fundamental research, he thought, is best done in the universities; but applied, or industrial, research is best done directly by industry in its own laboratories, and the more this work is located physically within the industry the better service it will give. In particular, only thus will the research really correspond with what industry needs, and while research done in a firm's own laboratory is seldom wasted, Dr. Blount is less certain about the adequate exploitation of that carried out in research associations or by other co-operative bodies. There is sometimes, as with the Therapeutic Research Corporation, the danger that member firms will only agree to the pursuit of lines of research in which they are not greatly interested. For a similar reason, Dr. Blount is critical of the location of research departments away from the factory; they are liable to miss the stimulus which an industrial enterprise, of which they are obviously part, can give, and at the same time are lacking in the inspiration that location in a university atmosphere can supply. Nevertheless, Dr. Blount thinks that there will always be much industrial research which requires organization co-operatively and that the research associations will have a place of continuing importance. With regard to government research, he thinks that every effort should be made on the civil side to transfer to industry or the research associations any investigations which they can properly handle; but just as industrial research requires to be located within industry for its efficient operation, so he would expect it to be necessary for a growing volume of government research to be located within the government organization. In regard to research management, Dr. Blount stressed the importance of the research manager, himself a scientist, not only having the greatest practicable freedom but also the fullest opportunity of understanding the outlook and interests of his fellow executives.

Nuclear Physics

A NEW monthly journal, *Nuclear Physics*, edited by Prof. L. Rosenfeld, of the University of Manchester, has been launched by the North Holland Publishing Co., Amsterdam, and Interscience Publishers, Inc., New York (1, No. 1; 1956. Subscription per vol. of about 700 pages: 53 fl., 14 dollars, 106*s*.; postage 8*s*.), and an important feature of it is its international character; this is ensured by the composition of its editorial board, which includes representatives from twenty-three countries where nuclear studies are pursued, including the U.S.S.R. and Hungary. The new periodical is devoted to the experimental and theoretical study of atomic nuclei, nuclear fields and the fundamental aspects of cosmic radiation and should prove an important and valuable addition to the rapidly growing number of scientific periodicals specializing in the field of nuclear energy. The first number contains five original articles and a progress report by P. H. Fowler (University of Bristol) describing the new results on elementary particles which were discussed at the Pisa conference held last June. R. K. Gupta and S. Jha (Tata Institute of Fundamental Research, Bombay), in their article on studies with the scintillation spectrometer, give a brief account of a single-crystal spectrometer (thallium-activated sodium iodide crystal), its calibration and its use for the examination of the gamma-ray spectrum of iodine-128. In another article E. P. George and G. S. Shrikanta (University of Sydney) present results of their observations of the energy spectrum of the cosmic radiation below ground. The underground exposures of Ilford nuclear research emulsions were made in a disused tunnel of the underground railway station at Holborn, London, at a depth equivalent to 57 m. of water. It is concluded that any explanation of the observed frequency of large-angle scatters of cosmic-ray particles underground in terms of a significant departure of the momentum distribution from that usually assumed can now be ruled out.

The editor adds a note on nomenclature to be used in the new periodical. The word 'electron' is to be used for particles with an elementary charge of either sign, and 'positon' and 'negaton' when it is desirable to emphasize the sign of the charge. The expressions 'isobaric spin' and 'isobaric quantum number' are to replace 'isotopic spin' and 'isotopic quantum number', respectively, and the latest nomenclature adopted by international agreement will be used for the elementary particles.

Cancérologie: New French Journal of Cancer Research

A NEW journal, *Cancérologie*, has been launched by the Anti-Cancer Centre at Lille to provide facilities for the publication of original papers by members of its staff and more particularly for the publication of more general papers, not usually acceptable to other cancer journals, given at annual symposia in the Centre. Emphasis is placed on the importance of these symposia for the communication of the results and ideas of a team of workers covering a wide range of clinical and laboratory observations on cancer. In the first number (pp. 98; from the Cité Hospitalière, Lille) many of the papers give convenient and adequate summaries and discussions of varied topics without aiming at the detailed analysis and documentation provided by other periodical reviews of cancer research. These will be of much more than local interest, especially to the general reader; the expert will often need to refer to other sources for fuller information and more complete references. Within the limits set by its editors, the journal therefore seems likely to fulfil a useful purpose.

A Large Sea Bass

A SPECIMEN of what may be the world's largest species of sea bass has just been added to the collections of the Smithsonian Institution. It is a 337½ lb. fish, 78½ in. long, the third of its kind caught near the Eniwetok Atoll in the South Pacific. The great sea bass is challenged for size only by some sharks and some members of the tuna family. The largest of the Eniwetok specimens weighed 414 lb. and was more than 81 in. long. This particular fish (*Promicrops lanceolatus*) has been well known for many years to northern Australians and is highly prized for food; but this is the first record for the Marshall Islands. It ranges from the South Pacific islands to Hawaii and the Red Sea and is closely related to the giant sea bass of the Atlantic and eastern Pacific known as the jewfish. The fish is related to the freshwater large-mouthed bass of the eastern United States but belongs to a different family. It is a deep-water fish and apparently an omnivorous eater.

Studies on Benjamin Franklin

THE American Philosophical Society has devoted an issue of its *Proceedings* (99, No. 6; December 1955) to "Studies on Benjamin Franklin" in celebration of the two hundred and fiftieth anniversary of his birth. Prof. W. E. Lingelbach discusses the relations of the Society with Franklin's writings and also "The Papers of Benjamin Franklin", a new edition of his writings now being prepared for publication under the auspices of the Society and Yale University. W. J. Bell, jun., writes on Franklin's relations with the German charity schools, E. Wolf on Franklin's Stamp Act cartoon, and Prof. C. W. Miller on "Franklin's Type: its Study Past and Present". R. L. Kahn contributes three Franklin–Raspe letters, and C. C. Sellers a note on Jane Mecom's little picture of Franklin. Kahn also writes on Franklin's relations with Grimm and J. H. Landolt, E. Dvoichenko-Markov on those of Franklin with Count M. A. Benyowski, and Prof. A. Pace on "The Franklin–Volta Correspondence: Legend or Fact ?". A long article by Prof. G. Chinard deals with "The Apotheosis of Benjamin Franklin, Paris, 1790–91".

Under the title "Panorama of Progress", the Franklin Institute has issued the January number of its *Journal* in honour of Benjamin Franklin. The most important of the international celebrations during the year are outlined by C. L. Jordan, chairman of the Anniversary Committee, and Prof. W. E. Lingelback writes on Franklin and the scientific societies. The remaining papers, which are planned to give a broad picture of the advances made in the physical sciences (pure and applied), in the social sciences and in economics since the birth of Franklin, are as follows: changing concepts in science (Lord Adrian), Franklin and one Plutonic year (Prof. Harlow Shapley), pioneers in electrical communications (E. Perucca and V. Gori), how medicine became a science (Sir Zachary Cope), Franklin and the unconquered fields of medicine (P. Lépine), Franklin's impetus to education (G. P. Harnwell), food and the future (D. P. Cuthbertson), science and agriculture (F. E. Bear), some aspects of Franklin's life in England (E. N. da C. Andrade) and Franklin the business man and apostle of free and competitive economy (M. L. Musante).

Zoological Nomenclature

THE International Commission of Zoological Nomenclature will start voting, as from June 30, on the following cases involving the possible use of its plenary powers: (1) *Bithynia* Leach, 1818 (cl. Gastropoda), validation; (2) *Osmerus* (cl. Pisces) as from Linnæus, 1758, validation; (3) *Phillipsinella* Novák, 1886 (cl. Trilobita), validation; (4) *Gempylus* Cuvier, 1829, and *serpens* Cuvier, 1829 (*Gempylus*) (cl. Pisces), validation; (5) Seguenziceratidae Spath, 1924 (cl. Cephalopoda, Order Ammonoidea), suppression; (6) *Lepisma* Linn., 1758 (cl. Insecta), gender for; (7) *Pagurus* Fab., 1775, and associated family-group name (cl. Crustacea, Order Decapoda), suppression. Full details have been published in the *Bulletin of Zoological Nomenclature* (11, Pts. 9 and 10; December 30, 1955).

In addition, an application is being made (*Bull.*, 9, Pt. 12; January 1956) for the use of the plenary powers in the following case: Curtis, 1837, 2nd ed. of "Guide Arrangement Brit. Ins.", suppression of, for the purpose of selection of type species of genera. Comments should be sent as soon as possible to the secretary to the Commission, Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

British Glaciological Society: Annual General Meeting

THE British Glaciological Society held its annual general meeting on December 8 in Bedford College, London, when a report was given on the Society's activities and its financial position during the past year. On behalf of the Society, Dr. G. C. L. Bertram presented an inscribed silver tray to Mr. Gerald Seligman in recognition of his long and continuing service to glaciology; Mr. Seligman has been president of the Society since its foundation in 1936 as the Association for the Study of Snow and Ice, and editor of the *Journal of Glaciology*.

A general discussion was held on the "Future Lines of Progress in Glaciology", and a full account will be published in the *Journal of Glaciology* (all contributions should be sent to the Editor, Little Dane, Biddenden, Ashford, Kent). The following were elected officers of the Society for 1956: *President*, G. Seligman; *Vice-Presidents*, J. M. Wordie, W. V. Lewis and K. Sandford; *Secretary for Scotland*, P. D. Baird; *Honorary Treasurer*, G. C. L. Bertram; and *Secretary*, Mrs. H. Richardson (c/o Scott Polar Research Institute, Lensfield Road, Cambridge).

Perkin Centenary Celebration

DURING May 7–10 the centenary of the production by W. H. Perkin of the first synthetic dye will be celebrated in London as follows. On May 7 overseas delegates to the Perkin Centenary Celebration will be received in the City of London at the Hall of the Worshipful Company of Tallow Chandlers. Four lectures will be given at the Royal Institution, Albemarle Street, London, W.1, and the first of these, "The Life and Work of Perkin", by Prof. John Read (University of St. Andrews), will be given in the afternoon of May 8, followed in the evening by a reception to delegates and guests at the Guildhall in the City of London. On the morning of the next day, Mr. Clifford Paine (development director, Imperial Chemical Industries, Ltd.) will give the second lecture, his subject being "The Development of the Dyestuffs Industry", and in the afternoon Mr. J. G. Evans (technical director of the Bradford Dyers' Association), speaking on "The Tinctorial Arts To-day", will give the third; the Perkin centenary banquet will be held in the evening, at the Dorchester Hotel, when the president of the Perkin Centenary Celebration, Sir Cyril Hinshelwood (president of the Royal Society), will be in the chair. On May 10 the fourth lecture, "The Development of Organic Chemistry since Perkin's Discovery", will be given by Sir Alexander Todd (University of Cambridge).

Domestic Heating in Great Britain

THE subject of domestic heating in Great Britain, which is of particular interest at the present time in view of the great changes that will be brought about by the forthcoming Clean Air Act and the programme of slum clearance, will be discussed at a conference arranged by the Institute of Fuel, to be held in the Assembly Hall of Church House, Westminster, London, S.W.1, during May 1–2. The first session will deal with fuels, including the possibilities of the production of smokeless fuel from coals hitherto considered unsuitable. The next three sessions will deal, respectively, with the design and application of appliances, the design of dwellings, and the planning and administration of smoke-control areas. The conference will end with a summing-up by a *rapporteur*, followed by open discussion. The sessions will be open to the public without charge. For enrolment as a member of the conference, non-members of the Institute of Fuel will be charged a fee of one guinea (half a guinea for those belonging to various participating bodies). Enrolment forms and further information can be obtained from the Secretary of the Institute of Fuel, 18 Devonshire Street, Portland Place, London, W.1.

Announcements

Prof. and Mme. Bernard Pullman, of the Theoretical Chemistry Laboratory, University of Paris, have been awarded the E.S.S.E.C. Prize for cancer studies (of value 1 million francs) for 1956 by the Ligue Française contre le Cancer. The award has been made for their work on the correlation between electronic structure and carcinogenic activity of molecules, and in particular for their book "Cancérisation par les Substances Chimiques et Structure Moléculaire" (Masson, Paris, 1955).

Dr. A. H. Sully, associate director of the British Steel Castings Research Association, has been appointed director of research in succession to Prof. R. J. Sarjant, who will continue to act in an advisory capacity to the Association.

The following have been appointed to lectureships in the University of Sheffield: R. Kilpatrick (pharmacology) and Dr. R. H. Tredgold (physics).

The following appointments have been made in the University of London: Dr. L. Pincherle, to the University readership in physics tenable at Bedford College; Dr. T. J. Williams, to the University readership in mechanical engineering tenable at King's College.

A symposium on "The Presentation of Science to the Public" is to be held in the Senate House, University of London, on March 21, under the chairmanship of Mr. A. L. Bacharach. The symposium is being organized by the Institute of Biology, the Royal Institute of Chemistry and the Institute of Physics. Principal speakers will be Dr. Archie Clow (B.B.C. Science Survey), Mr. A. W. Haslett (*The Times* Science Review) and Mr. J. McCloy (B.B.C. Television). Further information can be obtained from the Secretary, Institute of Biology, 41 Queen's Gate, London, S.W.7.

The annual general meeting of Science for Peace, to be held in the Holborn Assembly Hall, John's Mews, London, W.C.1, on March 10, will be followed (2–6 p.m.) by a public conference on "The Atomic Age—Perspectives and Problems". The speakers will include Prof. J. B. S. Haldane (on genetic effects of radioactive substances), D. G. Arnott (on the new outlook since the Geneva Conference), Prof. J. D. Bernal (on prospects for science in a world at peace) and Dr. E. H. S. Burhop (report of a sub-committee on disarmament). Tickets for the conference (price 2*s*. 6*d*.) can be obtained from Mr. B. Hayes, 72 Doneraile Street, London, S.W.6, or at the door.

The Institution of Chemical Engineers is holding a symposium and exhibition on "Modern Techniques in Chemical Plant Construction" on March 21 in the University of Birmingham. The papers at the symposium will cover three topics: some special constructional materials, with particular reference to their use by fabricators; fabrication and testing; and plant manufacture and erection. Further information can be obtained from M. G. D. Bailey, 1 Wentworth Gate, Harborne, Birmingham 17.

A symposium on the "Applications of Infra-Red Spectroscopy", organized by the Society of Chemical Industry, will be held in the William Beveridge Hall of the University Senate House, London, W.C.1, during April 9–10. A small exhibition on the same theme will be held in the Department of Chemical Engineering, University College, London. The fee for the symposium is £3 for non-members, and 10*s*. for members, of the Society. Application forms and further information can be obtained from the Assistant Secretary (Infrared Symposium), Society of Chemical Industry, 56 Victoria Street, London, S.W.1.

The Ministry of Agriculture, Fisheries and Food and the Department of Agriculture for Scotland are offering a limited number of postgraduate scholarships in agricultural economics, husbandry, statistics and agricultural and dairy engineering, for the academic year 1956–57. The closing date for applications is March 31. Further information can be obtained from the Secretary, Ministry of Agriculture, Fisheries and Food, Great Westminster House, Horseferry Road, London, S.W.1, or the Secretary, Department of Agriculture for Scotland, St. Andrew's House, Edinburgh 1.

Applications are invited for Lady Tata Memorial Fund grants, scholarships or fellowships from scientific workers of any nationality for research on diseases of the blood, with special reference to leukæmia, or any aspect of malignant disease connected with leukæmia, during the academic year October 1956–57. Grants are for research expenses: scholarships for personal remuneration (usually £600); and fellowships for workers with considerable research experience (£1,000). Application forms, to be returned by March 31, and further information can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, Chester Beatty Research Institute, Fulham Road, London, S.W.3.

Two scholarships tenable at research institutions in France during the academic year 1956–57 are being offered to British workers in medical science by the Medical Research Council on behalf of the Centre National de la Recherche Scientifique. They are intended for young graduates in medicine or science who have already had some experience in a branch of medical science, and are worth 50,000–70,000 francs a month, with a supplementary allowance (payable in sterling) for married men. A working knowledge of French is essential. Application forms, to be returned by March 31, and further information can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

To mark the completion of ten years of publication of the journal *Weather*, the Royal Meteorological Society is offering a prize of forty guineas for an essay of about five thousand words in English on "The Place of Meteorology in Liberal Education". Additional prizes may be awarded, and for these particular consideration will be given to entries from persons less than twenty-five years old. Entries must be sent in by December 31 to the Royal Meteorological Society, 49 Cromwell Road, London, S.W.7.

About £30 is available from the Clough Memorial Research Fund of the Edinburgh Geological Society for geological research in Scotland and the north of England (Northumberland, Durham, Cumberland, Westmorland and Yorkshire) during the period April 1, 1956–March 31, 1957. Applications for grants must be sent before March 31 to the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh 1.

Erratum. In the letter by C. H. Vincent on "The Gas Multiplier: a New Type of Electron Multiplier", published in *Nature* of February 25, p. 391, in the third and fourth lines for ". . . a highly stable electron-multiplication factor" read ". . . a high stable electron-multiplication factor".

COLONIAL RESEARCH IN THE BRITISH COMMONWEALTH*

The tenth annual report of the Committee for Colonial Agricultural, Animal Health and Forestry Research records total commitments of £2,042,000 for research in this field from Colonial Development and Welfare Funds from April 1, 1946, to March 31, 1954, although new grants during the year under review amounted to only £133,156. Of the approximately £8 million available for research for the period 1955–60, £2,730,000 has been allocated for agricultural, animal health and forestry research. With the completion of building activities and the assembly of additional specialists, research activities generally have increased, and the fruits of earlier work are now appearing with increasing frequency. Tribute is again paid to the large amount of willing assistance received from research institutions and specialists in the United Kingdom, and the collaboration between British and foreign specialists in tropical countries. The East African Agricultural and Forestry Research Council has been established, with wide powers of control over inter-territorial research in these fields, while the work of the East African Agriculture and Forestry Research Organization on soil-moisture relations and rainfall reliability is yielding valuable results in the control of water on large catchments, forest cover and erosion control and on crop-husbandry methods in areas of precarious rainfall. Much research into fertilizer requirements of tropical soils is proceeding, but a lot remains to be learnt about the nitrogen cycle under tropical conditions. Research in Northern Nigeria and Uganda has revealed a deficiency of sulphur in many areas which is limiting crop yields, particularly of groundnuts. The adoption of new techniques for micronutrient assessment has shown that in the Gambia and Uganda deficiencies of elements such as copper, molybdenum and boron that are required only in trace amounts may be curtailing crop yields.

Satisfactory progress has been made with soil surveys required for development plans, notably in British Honduras, Nigeria, Gold Coast, North Borneo, Aden and Somaliland. Much attention was given to cocoa, and the Cocoa Marketing Boards of Nigeria and the Gold Coast made further large grants to the West African Cacao Research Institute. The cocoa trade has accepted the very high-yielding Upper Amazon selections in West Africa as conforming to its quality requirements, so that these valuable types can now be issued to farmers, while very promising results have been obtained in breeding superior types of cacao. Research on swollen-shoot disease covered the migrations of mealybugs, which transmit the disease, the wild hosts of the virus and chemical methods for detecting latent infections. African farmers are now controlling black-pod disease of cacao in Nigeria; but control in the Gold Coast is less satisfactory. Notable features of the work of the West African Institute for Oil Palm Research are the studies on the nutrition of the palm and on diseases due to potash and magnesium deficiencies; a substation of the Institute was opened in Sierra Leone for the study of local problems. Promising new material was discovered in New Guinea by the Banana Collecting Expedition from the Imperial College of Tropical Agriculture, Trinidad, sent out in September 1954 as part of the long and complex breeding programme directed towards combating banana-diseases, while the cotton-breeding work and crop-husbandry trials of the research stations maintained chiefly by the Empire Cotton Growing Corporation have yielded extremely valuable results. Among plant selections valuable to farmers singled out in the report are improved groundnuts in Nigeria and Tanganyika (where forms resistant to rosette disease have been bred), new cottons for Uganda, Nigeria and Tanganyika, sugar-canes for British Guiana, Barbados and Mauritius, better sorghums for Nigeria, Gold Coast and Tanganyika, coffee selections in East Africa, rubber resistant to South American leaf blight, and maize resistant to South American rust.

Other work emphasized in the report includes that on pepper disease in Sarawak, leaf scald on sugar-cane in British Guiana, broadbean wilt in Cyprus, *Alternaria* leaf-spot disease of tobacco in Northern Rhodesia and Nyasaland, potato blight in the Cameroons and leaf-spot of bananas in the West Indies. The work on insect pests includes the control of coreid bugs attacking coconuts in the Solomon Islands Protectorate and Zanzibar, midges attacking millet in West Africa, rhinoceros beetles on coconuts in the Pacific area, termites in East Africa, longicorn beetles attacking cocoa in Grenada, aphis transmission of dieback of limes in the Gold Coast, and American bollworm on cotton in Tanganyika. Steady progress is being made with the Floras of Tropical East Africa, West Tropical Africa and Malaya, and preliminary work has been started on new Floras for Cyprus and the Central African region ("Flora Zambesiaca").

Veterinary research has been concerned particularly with the production of safe and effective vaccines for protection against rinderpest. The East African Veterinary Research Organization took over the manufacture of biologicals for the East Africa and Sudan regions during the year, and the research laboratories at Vom (Nigeria) continued to supply most of the needs of the West Africa region. Research is still needed to perfect the vaccines, and increased attention was given to tick-borne diseases, particularly East Coast fever, and to methods of tick-control on cattle, while studies on the African liver fluke and its intermediate snail host continued. At the Joint Animal Industry Division of the East African Agriculture and Forestry Research Organization and the East African Veterinary Research Organization, studies continued into the technique for measuring grassland productivity and into the accuracy of feeding trials, while studies of stock-raising on the intermediate savannas of British Guiana at the Ebini stock farm indicated deficiencies of cobalt and molybdenum as well as of phosphorus. Comparative studies in Fiji on heat tolerance in European and Zebu stock showed variations within breeds as great as between them, and in the Gold Coast, Nigeria and Northern Rhodesia investigations of cutaneous streptothricosis continued. Results are slowly emerging from the long-term animal breeding studies, and the commercial production of livestock in tsetse-infested areas with the aid of chemotherapy and controlled management and feeding was studied in Nigeria and Kenya, while studies of animal management in relation to cropping systems in African territories generally are pointing the way to more efficient farming methods. Extended investigations into pastures for tropical and sub-tropical areas were made in Northern Nigeria, Kenya, Trinidad and Fiji, and the work on nodulation of legumes in Kenya is of particular interest in relation to the nitrogen in tropical soils.

---

* Continued from p. 368.

Methods of forest regeneration were investigated in many territories, with particular attention to the use of non-toxic hormone preparations for killing tree-weeds in Uganda. Sylvicultural research in Cyprus for the regeneration of mountain forests and on eucalypt forests in the lowlands was extended. Forest-flora was investigated in Malaya and North Borneo, and the systematic botany of the Malayan region is now associated with the larger project for a new "Flora Malasiana" progressing under Dutch auspices. Failure of natural regeneration in juniper forests in Somaliland is now attributed to microclimatic changes following over-grazing, and considerable progress was made by a research unit in West Africa in assessing damage from boring beetles in felled timber in relation to species, seasons and bark removal.

The eighth annual report of the Colonial Insecticides, Fungicides and Herbicides Committee includes the usual account of the work of the Colonial Insecticide Research Unit at Porton, which was brought up to full strength by recruitment of an entomologist and a physicist, although the recruitment of a suitably qualified and experienced staff for employment both at home and abroad still presents some difficulty. Nevertheless, it is expected that the nucleus of younger scientists trained in the special techniques applicable to insecticide research now being built up will, in a few years, provide a pool of experienced men capable of taking charge of new units or projects and directing investigations. At Porton, investigations on the loss of effectiveness of insecticidal deposits from aqueous suspensions applied to mud walls have shown that loss of toxicity is due to rapid adsorption of the insecticide by the mud; and a survey of soils from various parts of the world showed that red lateritic soils are most active in adsorbing insecticides. No practical method was found of abolishing or reducing the adsorptive properties of Uganda soil. Studies of insecticidal surface coatings showed that the rate of loss of volatile insecticides from non-crystallizing films depends on the plasticizer urea–formaldehyde resin ratio and that the effectiveness of other synthetic resins as carriers for insecticides depends largely on the rate and extent of both hardening and permeability of the films. At the Imperial College Field Station, Selwood Park, investigations on the penetration of the insect integument by DDT solutions in lanoline showed that, in tropical application to *Protophormia terraenovae*, a fraction of the absorbed insecticide is taken up directly by the tissues, and experiments with oily deposits of 20-μ DDT crystals on an absorbent surface have now shown that the availability of particles to walking flies decreases logarithmically as the proportion of oil in the deposit increases. Studies on the persistence of insecticide deposits on glass plates and foliage continued at Rothamsted and investigations at Long Ashton on the tenacities of copper fungicides were completed in September 1954. In April 1954 the Committee took over from the Agricultural Research Council the preparation and publication of the Abstracts and News Summaries dealing with insecticides and herbicides, and plans for the publication of Fungicide Abstracts and News Summaries were also in hand.

The research unit at Arusha continued its investigations on the control of tsetse flies and mosquitoes, and the work with experimental huts at Taveta, now concluded, has shown that dieldrin at 30–40 mgm. per sq. ft. needs renewal at six-monthly intervals, irrespective of surface, but at 70–80 mgm. per sq. ft. persists for seventeen months on a mud and sand plaster. Extensive tests by the Insecticide Research Unit at Ilonga have shown that the main cotton pests (American bollworm and cotton aphis) can be controlled with a DDT/BHC mixture or endrin, but such control is unlikely to give profitable increases in yield on the peasant crop until standards of local agriculture have been improved. A programme of research on the distribution and bionomics of dipterous flies in Uganda was started in September 1954, and the Committee has also assumed responsibility for chemical investigations in connexion with the Western Sokoto Malaria Control Project in Northern Nigeria. The study of the ecology and habits of *Anopheles gambiae* in Mauritius continued, as well as the investigation in Fiji of the incidence and behaviour of mosquitoes and the determination of the vectors responsible for the transmission of filariasis. Research on the use of herbicides, arboricides and defoliants in East Africa was extended, and promising results were obtained with defoliants as an aid to tsetse-eradication. The report also directs attention to research in this field proceeding in the Colonies without the assistance of the Committee, such as that in Barbados on the control with soil insecticides of pests attacking the roots of sugar-cane, the promising results obtained in British Guiana with nicotine and chlordane sprays against *Castria daedulus* on coconuts, the extended campaign on the Gold Coast for control of *Sesamia* spp. and *Busseola fusea* in maize, that on the resistance of *Culex fatigans* to BHC in Penang, on the eradication of dhub grass (*Cynodon dactylon*) with sodium trichloroacetate at Samaru, Northern Nigeria, and on the control of the white stem borer (*Anthores leuconotus*) on coffee in Tanganyika with dieldrin.

The eighth annual report of the Colonial Economic Research Committee records studies at the West African Institute of Social and Economic Research of the working of the Niger Agricultural Project and of Gold Coast cocoa farmers' incomes with special reference to the abusa system, while the Economic Research Unit of the University College of the Gold Coast has completed the first stage of the periodical field investigations into movements of foodstuffs in the Accra region and has undertaken an economic survey of housing schemes in four main towns on behalf of the United Nations Mission. The Industries Branch of the Federal Department of Commerce in Nigeria has examined the economics of establishing fibre- and pulp-material industries, the production of gari and the operation of small craft, and the Commission for Technical Co-operation in Africa South of the Sahara and its scientific advisory council are taking an increasing interest in promoting inter-African co-operation in social and economic research.

The Tsetse Fly and Trypanosomiasis Research Committee has decided to set up special panels to deal with chemotherapy and with cartography and to advise on personnel questions. Its report for the year ended March 31, 1955, records that the problem of staffing the East African Tsetse and Trypanosomiasis Research and Reclamation Organization's new laboratory at Tororo is being overcome, that the East African Governments have agreed in principle to transfer the headquarters of the Organization to the Central Trypanosomiasis Research Laboratory there and that the title of the Organization is to be changed to "The East African Trypanosomiasis Research Organization". Much attention is being given at the Shinyanga laboratory to respiration and water exchange in *Glossina*, and it is intended to link research on the trypanosomes as closely as possible with research on the vector. The Mariakani experiment on the use of 'Antrycide' prosalt as a prophylactic has shown that cattle treated while under attack from tsetse with injections of the pro-salt every two months for more than two years acquired a resistance both to a local and an imported strain of *T. congolense*, which persisted for eighteen months after treatment ceased, and the experiment is being repeated on a larger scale at Kiboko in co-operation with the Kenya Veterinary Department. The Lambwe Valley settlement continued satisfactorily; an investigation into the effect of the arboricide 2.4.5-T on freshly cut stumps of thicket suggests that this substance may be of practical value in preventing regeneration, and in Ankole discriminative clearing against *G. morsitans* is going well.

An information bureau has now been completed at the Kaduna laboratories of the West African Institute for Trypanosomiasis Research. The Institute has collected data on the nature and spread of human trypanosomiasis in Ogoja Province, where the disease is characterized by a rapid invasion of the central nervous system, and measurements of a considerable series of blood sedimentation-rates for active cases of sleeping sickness confirm that the mean rate is exceptionally high in this condition and that the immediate effect of treatment with 'Melarsen' is to reduce the rate by about one half. Trials carried out in Benue and Ogaja Provinces in collaboration with the Nigerian Sleeping Sickness Service indicate that 'Melarsen' is well tolerated by patients treated under dispensary conditions. Further work on the establishment of *T. vivax* in rats suggests that clean serum provides a substance which protects the trypanosome from the rat's antibodies, that the active factor is present in lipid-free serum and that it is a component of serum protein. The cyclical transmission of *T. congolense* by *G. palpalis* was being studied, but investigations on the use of the curative and prophylactic salts of 'Antrycide' have passed largely from the laboratory to the field, although some work has been done on resistance to 'Antrycide'. Trials with a dose of 1 mgm./kgm. of 'Ethidium' bromide cured infections in Zebu cattle which had been produced by a blood-inoculated strain of *T. vivax*. At the Ugbobigha Field Station in Southern Nigeria, although the effects of topography and vegetation on the local distribution of the eight species of tsetse found in the vicinity of the Station was being mapped, research has been confined to *G. palpalis* and *G. longipalpis*. A pilot scheme has been initiated to assess the value of obstruction clearing as a practical measure of tsetse control. No major research into game or game conservation was undertaken, but the fact-finding survey of the major game species in Africa and the biological study of Thomson's gazelle in Tanganyika were nearing completion.

The annual report on fisheries research for 1954–55 of the Colonial Fisheries Advisory Committee reports that the allocation for fisheries research for 1955–60 is £930,000 and that the four vacancies for fisheries research officers at existing research stations should be filled during the coming year. The Inter-Territorial Fisheries Research Station at Jinja, Lake Victoria, has identified twenty species of *Tilapia* occurring in East Africa, and, as a result of ecological investigations which led to the discovery of several species of fish that feed mainly on snails, some of these species have been introduced successfully into dams, where they can be grown together with *Tilapia*. Work on the ecology and physiology of snails has shown that they play a valuable part in the biological economy of both large and small bodies of water. The East African Marine Fisheries Research Organization continued and expanded its work on the bottom fishes and the hydrography of the area, obtaining evidence that the stratification of the Indian Ocean in the deep waters extends right to the fringing reefs, while the data accumulated defining the water layers and changing depth of the upper thermocline between the East African coastal current and the waters of the Arabian Sea may be of very great importance in connexion with the plankton movements and the pelagic fishes. At the Joint Northern Rhodesia–Nyasaland Fresh Water Research Station the echo-sounder of the research launch *Gigipat* has given excellent results, and hydrological work continued, special attention being given to the productivity of coastal waters. The West African Fisheries Research Institute continued its fisheries exploration with the research vessel *Cape St. Mary* from Sierra Leone and the Gold Coast, and at the Freshwater Field Station at Birnin Kebbi, Northern Nigeria, a study of marine invertebrate fauna was in progress. The Fish Culture Research Station at Batu Berendam, Malacca, is expected to be completed at the beginning of 1957, and the Fisheries Research Unit at the University of Hong Kong was at full strength.

The report of the Director of the Anti-Locust Research Centre, on locust research and control during 1954–55, again emphasizes the heavy demands on the personnel of the Geographical Section by the further increase in the area invaded by the desert locust; 1,240 reports were received from thirty-six countries, and they became considerably more extensive, owing to the greater intensity of infestation. Statistical work has been mainly concerned with the analysis of photographs of flying locusts obtained during the field-work on swarm behaviour of the desert locust. Liaison is being maintained with the regional organizations and the insecticide industry with a view of testing new techniques likely to be of value in locust control. Detailed studies have suggested that BHC and DNC in their present formulations are comparable in toxicity, though the action of BHC is slower. The International Red Locust Control Service continued its detailed studies of methods of quantitative assessment of locust populations, their seasonal movements and the dynamics of vegetation in the outbreak areas. The situation with regard to the red locust in the Rukwa Valley in Tanganyika caused some anxiety, and it was also very grave with regard to the desert locust; the Arabian Peninsula continued to constitute a main source of danger, and the efforts of several governments, co-ordinated by the Food and Agriculture Organization of the United Nations, were still inadequate.

Research matters not covered by the reports of the specialist advisory bodies are relegated to a final section of the report and include the research of the African Studies Branch of the Colonial Office into problems of African administration and the noticeable expansion in the work of the Colonial Liaison Section of the Building Research Station, which nevertheless still finds it difficult to meet its present commitments. The work of the Section has included climatological studies, such as solar radiation in West Africa, the mechanism of heat transfer in building structures under tropical conditions, and the design of buildings for air-conditioning in the tropics, and a study of the fundamental causes of weathering of building materials in different climates is projected. Reference is also made to the Falkland Islands Dependencies Survey, a major task of which is topographical mapping of the Dependencies, and to the Geodetic and Topographical Surveys, where recruitment of field staff kept level with transfers and resignations. Good progress was made with geodetic surveys, and the triangulation and photo-control work over twenty-thousand square miles between Dar es Salaam and Jinja, in Tanganyika, and down into the Kilombero Valley, was completed as far as weather permitted.

The overseas scientific staff of the Colonial Geological Surveys was further increased from 196 to 202, but the number of vacancies has risen to more than thirty in consequence of the desire of some territories to enlarge their geological surveys. In some territories the fundamental task of mapping has been impeded by the diversion of geologists to other duties—for example, in connexion with the Volta River project and Tema harbour. Progress in establishing eight seismographs in the Windward and Leeward Islands and Trinidad is reported. Meteorological research was again somewhat restricted by the shortage of qualified meteorologists; but establishment of a separate research section of the East African Meteorological Department was being considered and the Department has continued to study the artificial control of rainfall and has used cetyl alcohol successfully to reduce evaporation from reservoirs. No laboratory work was carried out on Colonial road-research problems, but the Committee on Colonial Road Research has now been appointed. A report issued by the Colonial Road Research Liaison Officer on his visit to the Caribbean area in 1954 indicates that the basic problems for research there are much the same as in other Colonial territories, with an outstanding need to develop a method of pavement design suitable for traffic and sub-soil conditions in the various territories.

MECHANISM OF PHASE TRANSFORMATIONS IN METALS

A SYMPOSIUM on the "Mechanism of Phase Transformations in Metals" was organized by the Metal Physics Committee of the Institute of Metals and held in London at the Royal Institution on November 9. Nucleation and growth changes were considered during the morning session, when the discussion was based on an invited review paper by Drs. H. K. Hardy and T. J. Heal and on seven contributed papers. The afternoon meeting was devoted to martensitic changes, and there were nine contributed papers, in addition to a review paper by Drs. B. A. Bilby and J. W. Christian. Each session was introduced by a *rapporteur* (Dr. Hardy and Dr. R. W. Cahn), and there were fourteen speakers in the morning discussion and seventeen in the afternoon. In the circumstances, a comprehensive report is not possible in these columns, and this survey will merely mention some of the views that seemed important to me.

A pleasing feature of the symposium was the large number of speakers from abroad. Opening the morning discussion, Prof. A. Guinier (Conservatoire des Arts et Métiers, Paris) gave a masterly survey of recent work on the early stages of precipitation. He showed a series of remarkable electron micrographs (or radiographs), obtained by R. Castaing, using a new fine electron-beam technique with very thin solid copper–aluminium specimens. The θ' and θ'' (or Guinier–Preston [2]) precipitates were clearly visible, the latter being thin platelets of length about 1μ and thickness less than 100 A. At very high magnifications, a regular variation in the background is believed to show individual Guinier–Preston [1] zones. Prof. Guinier also directed attention to the distinction between Guinier–Preston zones in copper–aluminium alloys, which consist of enriched copper platelets in a uniform matrix, and those in aluminium–silver alloys, where the spherical silver-enriched regions are surrounded by silver-depleted regions of matrix. Similar 'complexes', though of different shape, are believed to occur in copper–nickel–iron and nickel–chromium–aluminium alloys, and to be responsible for 'side-band' phenomena in powder photographs.

Among the subsequent speakers concerned with pre-precipitation effects, Dr. A. Seeger (Max-Planck Institut, Stuttgart) suggested a dislocation model for the energetics of formation of Guinier–Preston [2] zones. Dr. J. Nutting (University of Cambridge) maintained the view already expressed in his paper with Mr. G. Thomas that white spots observed in electron micrographs correspond to the formation of Guinier–Preston [1] zones, and Dr. W. H. Taylor (University of Cambridge) said that M. E. Hargreaves's explanation of side-bands was essentially equivalent to that proposed by Prof. Guinier. Prof. C. S. Smith (Institute for the Study of Metals, Chicago) suggested the application of topological principles to segregates forming during the early stages of precipitation; it might be that growth of segregates occurs because an equilibrium array cannot be attained. Miss J. M. Silcock (Fulmer Research Institute) described some recent structural work, and Dr. A. Berghézan (Centre de Recherches d'Antony, France) emphasized the importance of imperfections produced by quenching or by external stresses.

Prof. G. Borelius (Kungl. Tekniska Hogskolan, Stockholm) showed that there are, after all, probably no large discrepancies between measured lattice diffusion-rates and the rates of early precipitation phenomena. He discussed the first stage of precipitation, which he called primary clustering, and which may be shown by electrical resistance measurements before detectable diffraction effects are produced. The paper given by Prof. Borelius, with Mr. L. E. Larrson, and some of his remarks, were concerned with lead–tin alloys, and Dr. O. Krisement (Max-Planck Institut, Düsseldorf) reported further work on this system. In contrast to D. Turnbull's results, he found that a single kinetic law did not apply at all temperatures, which suggests that the spinodal curve may have some influence. Krisement's description of the precipitation process, however, seemed to be closely similar to Turnbull's model of cellular precipitation.

Further remarks on precipitation from solid solution were made by Mrs. M. K. McQuillan (Metals Division, Imperial Chemical Industries, Ltd.), who described some anomalous effects in titanium–chromium alloys, and by Mr. F. B. Pickering (United Steel Companies) and Dr. G. Pomey (Irsio, France), both of whom discussed sigma phases in relation to the paper by Dr. H. J. Goldschmidt (B.S.A. Group Research Centre). Dr. Pomey showed that in some alloys nucleation is heterogeneous, and cold-working produces many more nuclei. Another topic at the symposium was the allotropic change in pure tin, which formed the subject of a paper by Dr. E. O. Hall (University of Sheffield). Dr. Groen (Technische Hogeschool, Delft) emphasized the different behaviour of pure tin and of tin–mercury alloys, and Prof. Smith suggested two simple experiments which might yield pure grey tin in compact form. The other papers of the morning session were concerned with precipitate morphology (Dr. H. I. Aaronson, Carnegie Institute of Technology), superlattice formation (Dr. H. Steeple and Prof. H. Lipson, Manchester College of Technology), and structural work on titanium–vanadium alloys (Miss Silcock, Mr. M. H. Davies and Dr. Hardy).

The afternoon discussion was opened by Prof. F. C. Frank (University of Bristol). He thought the crystallographic problems are now largely solved, but criticized the dilatation parameter used by J. S. Bowles and J. K. Mackenzie, since, if this represents an elastic strain, it implies an effective Poisson's ratio of -1. Prof. Frank drew an analogy with the cleavage of mica to emphasize that the experimental results should not be expected to agree exactly with predictions based on some simple theoretical postulate (for example, an invariant plane as the habit plane). A point of physical significance, still to be explained, is why in iron–carbon alloys there is an abrupt change in the habit plane as the carbon content is varied.

Prof. Crussard (Institut de Recherches de la Sidérurgie, Saint-Germain-en-Laye) presented views on martensite essentially different from those in the review paper. He described experiments to show that stabilization in retained austenite is due to the diffusion of carbon or nitrogen atoms, and suggested that nucleation is always partly dependent on thermal activation, although it is necessary in solids to consider the energy of elastic waves rather than to apply reaction-rate theory in the usual manner. In support of this, he cited recent experiments in the U.S.S.R. on isothermal transformation at liquid helium temperatures. Prof. Crussard believed that a dynamic approach is necessary in considering the growth process, which he likened to the propagation of a shock wave. Calculations based on this model are being made in collaboration with Dr. Krisement, and he believed that the compatibility equations will ultimately lead to the crystallographic criteria used in the phenomenological theories.

The conventional theories of martensite crystallography were discussed by Dr. D. S. Lieberman (University of Illinois), who described a simple graphical method for finding the habit plane in any transformation from the invariant plane strain condition, and by Dr. Bilby (University of Sheffield), who described the latest results obtained by the prism-matching and surface-dislocation approaches. Both he and Lieberman have found that a lattice invariant shear on a $\{111\}$ austenite plane gives approximately both the Kurdjumov–Sachs orientations and habit plane and the low-carbon $\{111\}$ habit plane without the need for dilatation or other length changes within the habit plane. Mr. R. Bullough, working at Sheffield, has obtained a general parametric solution for the habit plane for any set of lattice principal strains and specified shear elements. Other speakers on crystallography were Dr. T. Ll. Richards (Metals Division, Imperial Chemical Industries, Ltd.) and Dr. K. W. Andrews (United Steel Companies).

Transformations in low-carbon steels were dealt with by Dr. A. R. Entwisle (University of Sheffield), who presented convincing evidence that the habit plane is $\{111\}$, and by Dr. A. P. Miodownik (Battersea Polytechnic, London), who pointed out the rather anomalous position in which, since the formation of ferrite in pure iron sometimes produces relief effects, it is a martensitic transformation on Bilby and Christian's definition. Dr. Seeger discussed the transformation in cobalt with special reference to a contributed paper by Drs. F. Sebilleau and H. Bibring (Office National d'Études et de Recherches Aeronautiques) and reiterated his belief in the correctness of the dislocation–node model for this change. Dr. Christian (University of Oxford) referred to recent evidence obtained at Oxford by Mr. P. Gaunt that a macroscopic shape deformation occurs in both cobalt and the analogous $\gamma \rightarrow \varepsilon$ transformation in iron–manganese alloys.

The remaining papers contributed to the afternoon meeting dealt with the transformations in β-brass (Drs. D. Hull and R. D. Garwood, of University College, Cardiff) and in uranium–chromium (Mr. B. R. Butcher and Mr. A. H. Rowe, of the Atomic Energy Research Establishment, Harwell), the correspondence in the uranium transformation (Dr. W. M. Lomer, of Harwell), nucleation problems (Dr. M. A. Jaswon, of the Imperial College of Science and Technology, London), crystal geometry (Dr. Ll. Richards and Dr. W. T. Roberts), bainite reactions (Dr. Krisement and Prof. F. Wever) and the stabilization of austenite (Dr. S. G. Glover and Mr. T. B. Smith, of the University of Birmingham). Bainite was discussed by Dr. L. Habraken and Dr. Miodownik, the selection of the correspondence by Dr. Cahn (University of Birmingham), Dr. Lieberman, and Dr. Christian, stabilization by Mr. Kumar (University of Sheffield), and the thorny problem of isothermal versus athermal nucleation by several speakers. The meeting closed half an hour late with many people still wishing to contribute.

A minor point which emerged from both discussions was the dissatisfaction felt by several speakers with the present nomenclature. Prof. Smith pointed out that neither nucleation nor growth is the prerogative of nucleation and growth changes alone, and it was also felt that the present extension of the term martensite to cover the wide class of transformations which show a shape change in the transforming region is not wholly suitable. The difficulty about such a situation, of course, is that the existing usage is established; the problem has arisen largely because the kinetic features on which Greninger and Troiano based their classification of transformations have gradually had to be replaced by other criteria.

In conclusion, it is necessary to applaud the care and thoroughness with which the two *rapporteurs* managed to summarize so much material, and the success of the chairmen (Profs. G. V. Raynor and A. G. Quarrell) in keeping speakers to their allocated times. The papers and discussion will be published in the Monograph and Report Series of the Institute of Metals. J. W. CHRISTIAN

BIOLOGISTS AND NATIONAL SERVICE

THE Institute of Biology has made inquiries of the Ministry of Labour and National Service about the opportunities open to graduate biologists in the Services (*J. Inst. Biol.*, 3, No. 1; November 1955). The position appears to be as follows. All science and engineering graduates entering the Forces are considered for National Service commissions, and in the past about 40 per cent of them have been commissioned during their National Service. Both in the Royal Navy and the Royal Air Force, science graduates are accepted for National Service only if they can be recommended by a pre-call-up officers' selection board for a National Service commission. In the Army all graduates are called up in the ranks; but each is given an opportunity of being considered for a National Service commission during the period of his basic training.

There are comparatively few opportunities for a graduate in the biological sciences to be employed in any of the three Services in a capacity which will make direct use of his qualifications. So far as the Navy is concerned, his acceptance is unlikely. The demands of the Navy are mainly for mechanical and electrical engineers, mathematicians and physicists, and it does not usually have any requirement for graduates in the biological sciences. In the Royal Air Force, a comparatively small number of graduates in biology is accepted for National Service commissions in the Education Branch. It is also open to any National Service recruit to opt for service in the General Duties Branch for training as a pilot.

The War Office has recommended that a graduate in the biological sciences should apply for service in either the Royal Corps of Signals, the Royal Artillery, the Royal Engineers or the Royal Armoured Corps, where his scientific background is likely to be particularly valuable. There is, of course, nothing to prevent a science graduate from applying for service in any branch, technical or non-technical, and acceptance for a commission will depend solely on qualities of leadership and character and does not depend on technical or academic qualifications, except in so far as a potential officer must be intelligent and able to express himself clearly. Commissions in the Royal Army Education Corps are not given to National Service men; but a graduate in biology, especially if he holds the postgraduate Certificate of Education, may elect to do his service in that Corps where he could expect to be appointed sergeant instructor. The Royal Army Medical Corps is normally officered by medically qualified men; but an occasional vacancy occurs for a physiologist, biochemist or entomologist in commissioned rank. Otherwise, biology graduates may be appointed as laboratory technicians or in similar posts, and promotion to sergeant rank is possible.

An increasing number of science graduates now apply for short-service commissions as an alternative to National Service. These are voluntary regular engagements and usually involve a minimum of three years full-time service. Short-service commissions are available for science (including biology) graduates in the Education Branch of the Royal Air Force or in the Royal Army Educational Corps, as well as in other branches of the Royal Air Force and the Army.

There is no 'allocation' of scientists to defence work; but there is a number of projects of high priority carried on by government departments and private firms on which science graduates may be employed and given deferment on the applications of the government department concerned. Most of the vacancies are for physicists, mathematicians, chemists and engineers: biologists are required only on rare occasions. Deferment can also be granted for certain appointments in the Colonial Agricultural Service, for which biologists are much more in demand.

INTERNATIONAL SURVEY OF PROGRAMMES OF SOCIAL DEVELOPMENT

IN accordance with a resolution of the United Nations Economic and Social Council, the Bureau of Social Affairs of the United Nations Secretariat, in co-operation with the International Labour Office, the United Nations Educational, Scientific and Cultural Organization, the Food and Agriculture Organization and the World Health Organization, has prepared a survey of national and international measures taken to improve social conditions throughout the world*. Entitled "International Survey of Programmes of Social Development", it is concerned primarily with measures taken since 1945, and with those taken by governments rather than by voluntary or private organizations, and is intended to supplement the "Preliminary Report on the World Social Situation". The survey brings out the remarkable recent expansion of such programmes throughout the world, an expansion which has necessitated the report being limited to the outlining of trends and developments, using concrete cases only for illustrative purposes. The report should be particularly useful to all concerned with Colonial development and welfare and with technical assistance generally, whether under the Colombo Plan or in other ways.

An introductory chapter reviewing the similarities and differences in national approaches to social welfare, production and rural development points out that, in practically all the types of programme surveyed, the three problems constantly being encountered are those of obtaining adequate personnel to execute the programmes, adequate information to guide them, and adequate resources to finance them. Shortages of trained personnel are experienced by countries at all levels of development. Training abroad on fellowships has made an important but limited contribution to the supply of the higher-level technical and professional workers in some countries; attempts have been made in many countries to deal with the maldistribution among the professions, and the less-developed countries are increasingly turning to auxiliary workers, or technical assistants.

---

* International Survey of Programmes of Social Development. Pp. iv+200. (New York: United Nations; London: H.M.S.O., 1955.) 2 dollars, 15s., 8 Sw. fr.

The problem of obtaining adequate information for social programmes is in part that of balancing the use of limited resources; but reliance on social research as a basis for formulating, checking and evaluating systematic plans and programmes is increasing, and more attention is being given to experimentation and small trials before launching large projects. In regard to finance, however, there is little agreement as to what constitutes balanced development or a balanced allocation of funds for simultaneous economic and social development, or as to the order and timing of expenditures on different types of programme; nor does a chapter in the survey dealing specifically with research and surveys in connexion with social programmes warrant any confidence that a more detailed framework of thought to guide specific decisions is either possible or desirable.

This chapter is well documented and gives a brief picture of the organization of government research in various countries, as well as of such recent developments in the technique of research into social problems as the sample survey and the interdisciplinary approach, known as operational research. While, however, the increase in government statistical activities, especially in the under-developed areas, is emphasized, little information is given, or appears to be available, as to expenditure on social research. In the United States it amounts to some 2–3 per cent of the Federal expenditure on research, but no figures are given for other countries. In Norway, public research expenditure rose from 14·7 million kroner in 1938 to 83·4 million kroner in 1952, and total expenditure on public and private research and development (both civil and military) is estimated at about 1 per cent or more of gross national expenditure in the German Federal Republic, Great Britain, the Netherlands, the United States and the U.S.S.R. In the economically developed countries, non-military research expenditure appears to be between 0·3 and 1 per cent of national income, but in undeveloped countries it is much less. During the decade ending 1952, population censuses were conducted in 155 out of 239 areas of the world, covering nearly 60 per cent of the world's population. Ninety-five countries and territories have taken on agricultural censuses within the framework of the 1950 World Census of Agriculture, and since 1948 more than thirty countries or territories have published a general statistical bulletin for the first time. In general, however, the role of the social scientist in relation to social policy appears to be uncertain.

The remaining chapters of the survey deal separately with health, nutrition, education, labour and social security programmes; with the programmes to improve housing and community facilities and to aid the consumer; and with special programmes of social protection and rehabilitation, or of social development for rural areas; and with general approaches to social development.

A DIETARY DEFECT IN MAIZE DEVELOPED DURING TREATMENT WITH LIME

By P. L. PELLETT and PROF. B. S. PLATT, C.M.G.

Human Nutrition Research Unit, Medical Research Council Laboratories, Hampstead, N.W.3

IN a recent appraisal of the state of knowledge on pellagra[1], it was agreed that the problem of the pellagragenic properties of maize is not yet solved and that the etiology of the disease is by no means simple. The incidence of pellagra is reported to be low in some regions of Mexico where the consumption of maize is high; the explanation of this is not clear—it may be that the disease is not diagnosed or reported, that the diet contains some foods, for example, beans, which protect the consumer, or it may be the result of the method of preparing the maize grain for making tortillas. The last of these possible explanations has led to several investigations on the effects on the nutritive value of maize when treated with lime in the Mexican manner.

Krehl *et al.*[2] found no difference between rats fed on lime-treated or raw maize. However, Laguna and Carpenter[3], Cravioto *et al.*[4] and Squibb *et al.*[5] reported that rats fed on lime-treated maize grew better than rats given untreated maize; these results have been confirmed in our laboratory. Recently, Braude *et al.*[6] reported the curative effect on pellagra in pigs of maize which had been partially hydrolysed with sodium hydroxide; but Goldsmith *et al.*[7] were unable to demonstrate any beneficial effects of lime-treated maize in human pellagrins.

The effect of lime on the nutritive value of maize has been ascribed either to an increase in 'available' nicotinic acid following hydrolysis with alkali of a 'bound' form[3,6], or to the racemization of certain amino-acids, thereby avoiding amino-acid imbalance in the diet[4]. The highly critical nature of the balance of amino-acids for growth has been emphasized in a recent paper by Elvehjem and Harper[8].

The diets of the rats in the three previously reported experiments on the effect of lime-treatment of maize have contained adequate amounts of the known B-vitamins except nicotinic acid, the investigators having been concerned primarily with the effects of lime on the availability of nicotinic acid. However, since lime-treated maize, when substituted for untreated maize in human dietaries, may not be combined in diets with foods supplying adequate amounts of B-vitamins, experiments have been made on the effects on rats of diets consisting mainly of lime-treated or untreated maize and without supplements of the B-vitamin complex.

The results obtained in three separate experiments are summarized in Table 1, from which it can be seen that: (i) the rate of growth of the rats fed on lime-treated maize was significantly lower than that of the rats on untreated maize; (ii) supplementation of the diet with either nicotinic acid or tryptophan had no effect on this depressed growth-rate; (iii) on addition to the diet containing lime-treated maize of aureomycin or of a mixture of B-vitamins, the

Table 1. WEIGHT GAINS OF RATS UPON RAW AND LIME-TREATED DIETS WITH AND WITHOUT VARIOUS SUPPLEMENTS

Experiment	Diet (*a*)			No. of rats	Average weight-gain (4 weeks) gm	Average weight-gain per 100 gm. food eaten (4 weeks) gm.	*P**
	No.	Maize	Supplement				
A	I	Raw	None	6	59·3	23·5	< 0·001
	II	Lime	None	6	40·5	18·9	
	III	Raw	Aureomycin (*b*)	6	65·2	24·9	
	IV	Lime	Aureomycin (*b*)	6	64·7	25·1	
B	I	Raw	None	6	56·5	21·8	< 0·01
	II	Lime	None	6	39·5	18·1	
	III	Raw	Aureomycin (*b*)	6	53·2	20·8	
	IV	Lime	Aureomycin (*b*)	6	50·0	21·6	
	V	Raw	Nicotinic acid (*c*)	6	58·7	22·6	
	VI	Lime	Nicotinic acid (*c*)	6	37·3	16·6	
C	I	Raw	None	6	49·7	21·7	< 0·001
	II	Lime	None	6	27·3	15·0	
	VII	Raw	B vitamins (*d*)	6	64·8	23·9	
	VIII	Lime	B vitamins (*d*)	6	60·2	23·0	
	IX	Raw	Tryptophan (*e*)	6	50·0	20·1	
	X	Lime	Tryptophan (*e*)	6	27·8	15·0	

* Analysis of variance technique used. Effects of diet differences shown to be highly significant when results of weight-gain per 100 gm. food were analysed.

(*a*) Diet: casein (alcohol extracted) 3 per cent, salt mixture (de Loueiro) 4 per cent, sucrose 5 per cent, lard 3 per cent, maize (raw or lime-treated) 85 per cent. The method of lime-treatment of maize was that of Cravioto (ref 9).

(*b*) Aureomycin: 10 mgm. per 100 gm. diet.

(*c*) Nicotinic acid: 3 mgm. per 100 gm. diet.

(*d*) B vitamins (all per 100 gm. of diet): choline 200 mgm., inositol 100 mgm., para amino-benzoic acid 44 mgm., thiamine hydrochloride 1·0 mgm., riboflavin 1·2 mgm., pyridoxine 1·0 mgm., calcium *d*-pantothenate 2·0 mgm., biotin 0·2 mgm., folic acid 0·6 mgm., nicotinic acid 3·0 mgm.

(*e*) Tryptophan. 100 mgm. per 100 gm. diet

growth-rate was the same as that of rats on a diet of untreated maize.

It was suspected from a consideration of these experiments that the lime-treated maize contained less of some of the vitamins of the B-complex than untreated maize, probably of those known to be required for growth and alkali-labile, namely, riboflavin and thiamine. According to Cravioto *et al.*[9] vitamins are not destroyed during lime treatment; but Zozaya and Alvarado[10] have reported that riboflavin was absent from tortillas and Squibb *et al.*[5] have reported losses of 32–42 per cent of total nicotinic acid during lime treatment.

Analysis of raw and lime-treated maize for total nicotinic acid, riboflavin and thiamine revealed (Table 2) considerable losses of all three vitamins during lime treatment and, since it was known from previous experiments that additions of nicotinic acid did not affect the depressed rate of growth, the possibility that it was due to insufficiency of riboflavin or thiamine was investigated.

Table 2. VITAMIN CONTENT OF RAW AND LIME-TREATED MAIZE

Vitamin	Method of analysis	Content in µgm/gm (water content 9–10 per cent)	
		Raw	Lime-treated
Nicotinic acid	Microbiological: *Lactobacillus arabinosus*	18·0 18·6	12·0 10·5
Riboflavin	Microbiological: *Lactobacillus casei ε*	1·4 1·6	0·6 0·8
Thiamine	Chemical: thiochrome	5·3 5·0	1·0 1·1

The results in Table 3 show that addition of either riboflavin or thiamine to lime-treated maize produced an increased growth-rate as compared with that of the control animals.

The effect of riboflavin was much greater than that of thiamine, and the weight gain on the former of about 2·2 gm. per rat daily is close to that of 2·1 gm. per day for rats of similar weights on the diet with the vitamin B-complex supplement. It appears, then, from these results that the main cause of the retarded growth of animals on lime-treated maize is an inadequate amount of riboflavin consequent on destruction during lime treatment of the grain; the thiamine intake is probably marginal and the growth increase obtained with aureomycin may be due to a vitamin-sparing action effected in some way by the microflora of the gut of the rat.

The low incidence of pellagra reported from Mexico and the possibility of this being due to the alleged beneficial effects of lime-treated maize has led to some trials in Southern Rhodesia[11] with a view to the introduction of the process into a region in which the prevention of pellagra is a problem.

The substitution of lime-treated for whole maize meal would have the merit of increasing the amount of calcium in the diet, of raising the proportion of the total nicotinic acid in the grain in 'available' (that is, unbound) form, though from Table 2, about a third of the total may be lost and, since the 'bran' of the grain is removed in lime treatment, digestion and absorption of the treated product might be improved.

The disadvantages would include substantial reduction in the amounts of riboflavin and thiamine.

Table 3. AVERAGE WEIGHT-GAINS OF ANIMALS FED ON LIME-TREATED MAIZE AND SUPPLEMENT OF RIBOFLAVIN OR THIAMINE

Diet	No. of rats	Initial average weight (gm.)	S.E.*	Average weight after 10 days dosing (gm.)	S.E.*	Average weight gain (gm.)
Lime-treated maize	4	62·5	6·1	69·0	7·3	6·5
Lime-treated maize + riboflavin	4	56·0	3·3	78·0	3·8	22·0
Lime-treated maize + thiamine	4	61·7	3·8	75·0	4·8	13·3

* Standard error of the mean.

All animals had previously been on a lime-treated unsupplemented diet for 4 weeks. The supplements were 150 µgm. daily of riboflavin or thiamine for a period of 10 days.

The amount of riboflavin in the traditional diets of the tribes of Central Africa having maize as their staple food may be low. Platt and Webb[12] estimate a content of 1·13 mgm. riboflavin for a 3,060 Cal. diet (not containing grain 'beer'); the allowance of riboflavin recommended by the British Medical Association Committee[13] is 1·8 mgm. for a male adult on a 3,000 Cal. diet. In the dietaries of sophisticated African communities whole maize meal (machine-milled grain) frequently replaces the domestically prepared maize flour, and in such dietaries the amount of vegetables and fruit, which are important sources of riboflavin, is often much less than in the traditional dietary.

It is important in this connexion to note that one of us (B. S. P.) has worked throughout the year in the Central African territory of Nyasaland, where the people obtain sometimes as much as three-quarters of their energy from maize, and yet, in the rural areas, pellagra was never seen. The maize flour used was prepared by the women by a process widely used throughout Africa which includes soaking and fermentation. The use of such flour may have contributed to the absence of pellagra; the extensive consumption of grain 'beer'[14] may also be a factor[12,14].

We are grateful to the Lederle Laboratories Division of Cyanamid Products, Ltd., for their gift of a sample of aureomycin and to Dr. V. Mikulicic, a World Health Organization Fellow, for his assistance in the later stages of the above work. [Nov. 22

MEANING OF DEUTERIUM ABUNDANCE IN METEORITES

By Dr. GIOVANNI BOATO
Istituto Fisico dell'Università, Genova

THE article by G. Edwards on the "Isotopic Composition of Meteoritic Hydrogen"[1] contains some very questionable statements about the meaning of the deuterium content of meteorites and an incorrect interpretation of the results and conclusions reached by me on the same subject[2].

The significance of the determination of the D/H ratio in planetary objects in connexion with the problem of the origin and the formation of the solar system was pointed out a few years ago by Urey[3] and by Kuiper[4] and was discussed in detail more recently by me[2a]. Some further comments can be added here.

The isotopic evidence may be used in the following way. First, it is necessary to determine whether there is a definite difference between the deuterium content of the Earth and that of meteorites, these last being regarded as our only specimens of the material present in the planetary space outside the Earth. A definite difference, namely, a difference of more than one average fractionation stage, would suggest that an enrichment process other than ordinary chemical fractionation had operated on the hydrogen isotopes at some time between the initial accumulation of the planetary bodies and the present time. The lack of such a definite difference in the carbonaceous chondrites, together with the other experimental evidence, suggested to me that the primeval cosmic abundance of deuterium could not be different from the terrestrial abundance within a factor of the order of a chemical fractionation stage. Such a conclusion is supported also by the data of Edwards on the iron meteorites.

The second step to be taken is a more detailed study of deuterium abundance in different types of meteorites and different hydrogen compounds, in order to understand which fractionation processes are responsible for the observed variations. This kind of work requires a large number of analyses, carried out in a systematic manner, since the experimental method is delicate and additional evidence is generally lacking. Thus I feel that the limited amount of knowledge on the origin of the meteorites and the small number of deuterium analyses make meaningless at the present time such questions as whether the D/H ratio in the iron meteorites is more 'reliable' than the D/H ratio in carbonaceous chondrites, as Dr. Edwards tries to prove in his article. The detailed reasons for this will be given at the end of this article.

In attempting to demonstrate that his results are more conclusive than mine, Dr. Edwards makes two main criticisms of my work: (1) that I "attached special significance" to some specific results; (2) that my analytical data may be wrong, since Wiik[6] found systematically higher water contents in his chemical analyses of the carbonaceous chondrites.

So far as the first point is concerned, my interpretation of the significance of the *four* results showing deuterium content outside the range of terrestrial variations was clearly stated. It was only one additional proof that we were dealing with true meteoritic water, but it was never stated that "special significance [was attached] to the three results in which he found deuterium to be more than 25 per cent higher than in Lake Michigan water" (quote from Edwards's paper). I would like to emphasize that I never said that the concentration of deuterium in the planetary space was 25 per cent higher than that on the Earth.

The second point, that is, the difference between Wiik's results and mine on the total water content, needs a little more attention. The reason for the divergence—which Dr. Edwards perhaps did not think of—is clear: Wiik used the Penfield method, which is carried out at atmospheric pressure, whereas in my combustion apparatus the powdered meteorite was previously placed in a vacuum—a procedure that was considered correct, since the meteorites are coming from the perfectly evacuated interplanetary space. Thus, an outgassing of the powder took place, with the result that all the water loosely adsorbed (and undoubtedly atmospheric) was given off very rapidly. Consequently, this water is not given in my paper (Tables 2 and 3)[2b], whereas I took into consideration the water extractable in a vacuum at higher temperatures. On the contrary, the Penfield method, used by Wiik, gives the total water content, which is comprehensive of *all* adsorbed atmospheric water. It is not surprising that this total water can amount to 20 per cent of the meteorite in weight, since carbonaceous chondrites are very porous stones; in one experiment, I found a 10 per cent increase of weight in a sample of Cold Bokkevelt left for a while in an atmosphere saturated with water vapour at room temperature.

Incidentally, it should be noted that the method I used for the determination of water was thoroughly checked for quantitative recovery by repeated runs with small 'Pyrex' tubes containing known amounts of water of known isotopic composition, since a total yield was the necessary condition for obtaining no isotopic fractionation during the processing.

One possible objection to my method could be raised, namely, that I used a temperature too low for a complete extraction, since some hydrated silicates are known which give off their last amounts of water at very high temperatures. I had a maximum temperature of 800°–900° C. and did not check if some water was extractable at higher temperatures; however, Penfield's method does not use higher temperatures either. On the other hand, that the incomplete extraction *cannot* be the reason for my four higher D/H ratios was proved by the fractional extraction of water in a vacuum at different temperatures[2b]. In this respect, my results seem to be in complete disagreement with the finding of Godfrey[5], cited by Edwards, since I constantly found that the stone, and not the extracted water, becomes enriched in deuterium with rising temperature.

The question as to the meaning of the results remains to be discussed. As is generally known, irons and stones (to which group the carbonaceous chondrites belong) are two completely different types of meteorites; their origin and mutual relationships are still somewhat obscure. A detailed discussion of the meteorite problem, based on the best available experimental evidence, was given by Urey and Craig[7], who found that the ordinary chondrites fall into two distinct groups with respect to the total iron content. These two groups very likely represent the two parent bodies of the meteorites, that is, two asteroids which came into collision and broke apart. The same authors attempted to give an explanation of the formation of the meteoritic material prior to the final collision, in the light of present views on the origin of the planetary system and dissipation of volatiles from the protoplanets[8,9]. The process was certainly extremely complicated, involving high temperatures, chemical reactions and repeated breaking and mixing up of material. At the time that paper was published, no good analyses of the carbonaceous chondrites were available, and no clear relationship was apparent between these stones and the ordinary chondrites; therefore, no definite conclusion could be reached by Urey and Craig about these objects. Since then, Wiik[6] has carried out complete analyses of many carbonaceous chondrites, and it turned out that they belong very definitely to Urey and Craig's 'high' group of chondrites, that is, that they have exactly the same chemical composition of these stones, as far as the non-volatile constituents are concerned. On the other hand, there are large variations in the volatile elements, namely, oxygen, sulphur, hydrogen (mainly as water) and carbon. It appears, then, that the carbonaceous and the 'high' group ordinary chondrites are closely correlated and that they derive from each other through the simple dissipation and/or condensation of volatiles.

Unfortunately, no definite evidence has been found as to whether the carbonaceous chondrites represent a sample of the primordial cosmic material, as Urey had postulated some years ago[3,10]. On the contrary, their relationship to the 'high' group of chrondrites is a point against this hypothesis, if one accepts the theory of Urey and Craig that the 'low' group represents more nearly the primordial material.

In any event, while the carbonaceous chondrites were never heated at very high temperatures, since they have partially preserved their volatiles, the iron meteorites were probably formed by a high-temperature reaction of silicates or oxides with hydrogen gas. In these circumstances, no clear way can be seen for a comparison of the hydrogen isotopic composition of irons and carbonaceous chondrites. In the first meteorites the hydrogen is contained as dissolved hydrogen gas in the metal and/or as some hydrogenated compound in the minute discontinuities between the nickel–iron crystals (this point is not clear in Edwards's paper); in the carbonaceous chondrites the hydrogen is mainly in the form of combined water and possibly a few per cent of it is present as organic material. It is seen that the fractionation processes which eventually produced the observed difference in isotopic composition were certainly of a complicated nature, and any assumption at the present time would be pure imagination.

Thus, it is not possible to deduce, from the present data, the exact isotopic composition of the primordial hydrogen. For this reason, the final conclusions reached by Edwards are devoid of meaning. On the other hand, if one assumes, with Edwards, that the primeval abundance of deuterium was indeed that of the iron meteorites, one cannot see how the same abundance can be assumed for the primitive Earth, since mainly water and not hydrogen gas was retained by the gravitational field and it would seem almost certain that these two compounds did not have the same isotopic composition. In fact, kinetic fractionation processes were certainly operative and, if an equilibrium condition was established, then very likely sufficiently low temperatures were present to produce a remarkable fractionation.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Hormones and the Cytoskeleton

THE object of this communication is to present the hypothesis that hormones modify the 'cytoskeleton' of the cell. Though I have held this view for some time, and have discussed it with others, I have not advanced it formally, because until now it did not appear to be useful. There are, it is true, subcellular actions which have been described for hormones; notably one may mention the interesting effects of thyroxine upon the oxidative phosphorylation of mitochondria which formed the basis of a recent lecture to the Third International Congress of Biochemistry by C. Martius. There are also conclusive observations upon the action of insulin in altering permeability to sugars[1,2]; and also, on the contrary, the widespread idea that insulin controls the formation of glucose 6-phosphate. Yet in spite of interest in these facts, there is a general feeling that hormones act upon the cell as a whole, and that their action is somewhat diverse rather than being upon one enzymic or other step (cf. A. Beloff-Chain *et al.*[3], and see particularly the discussion of this by O. Hechter[4]). It is from this aspect that I think the 'cytoskeletal' view may prove to be a useful working hypothesis.

Many years back I became impressed by the idea that to view the cell as a bag of enzymes, however specific these might be in their action, could not account for the integrated behaviour of cells, any more than disorientated carbon atoms could account for the reactions of the benzene ring; and I felt forced to postulate the presence of a fluid anatomy in the geography of the cell, being some tenuous network by the action of which the cell's enzymic activities were co-ordinated. (The term 'cytoskeleton' was given to this by J. Needham; it is a good description provided that it does not convey the idea of the rigidity of a bone.) Other biologists have felt the difficulties in accounting for the whole actions of cells, too, and a critical discussion of pros and cons may be found in the book "Cytology and Cell Physiology"[5]; see also ref. 6.

The 'cytoskeletal' hypothesis has met with some hostility, both from those who consider wrongly that it excludes the essential studies on isolated enzymes, and also from those who feared it might be a return to the long-discarded ideas of the giant molecule. Belief in the presence of intracellular structures has been made easier by recent electron microscopy of mitochondria (by Palade[7] especially and by other work); by the now known existence of nucleic acids in the cytoplasm, and by the recent report of the existence of cytoplasmic membranes seen by Palade. (I am indebted to Dr. E. F. Gale for telling me of these observations, reported to the Ford Enzyme Symposium on November 2, 1955.)

Whether the cytoskeleton consists of continuous thin membranes, or whether it is arranged like the bentonite gel by rapid re-formation of oriented particles, or by more classical chemical links or by hydrogen bonds—whichever way it takes place is immaterial from my present point of view. It has always been to me an obvious consequence of the 'cytoskeletal' idea that it was the cytoskeleton rather than individual enzymes which was the co-ordinating factor, as it were the master structure of the cell this was pointed out by me some twenty-five years ago and is an essential emphasis in my point of view Hence an agent which could change the cytoskeleton might be expected to modify several enzymic reactions simultaneously by giving a new direction to this fluid anatomy.

Hormones are active in small amounts, and it is definitely conceivable that very small amounts of peptide or steroid structures could enter the surface of cells and accomplish such an orientation. This is the reason why it is here advanced that a hormone re-orientates the cytoskeleton. From the point of view of this working hypothesis, the search for some one enzymic reaction which a hormone modifies is doomed to failure, and further efforts should be directed to clarifying the patterns of diverse reactions which may be modified by the actions of hormones upon whole cells.

An Antigen determining Virulence in *Pasteurella pestis*

DESPITE assiduous search by many workers, the factor conferring the property of high virulence of strains of *P. pestis* has remained undetected. Virulen and protective avirulent strains have been studied comparatively by the methods of immunology immunochemistry and biochemistry without yielding convincing evidence of a difference in their properties sufficient to account for their difference in virulence This communication reports results showing that an important antigenic difference between virulent and protective avirulent strains does in fact exist.

It has been demonstrated that virulent and avirulen strains can be differentiated on the basis of ability of the former and inability of the latter to develop resistance to phagocytosis by mouse polymorphonuclear leucocytes under well-defined conditions *in vitro*[1]. Virulent organisms harvested from growth on nutrient agar incubated at 28° are highly sensitive to phagocytosis; I term these *V/S*. When they ar incubated, with gentle rotation, for 3 hr. at 37° in tubes of tryptic-digest meat broth at *p*H 7·0, they become resistant to phagocytosis; virulent organisms so treated I term *V/R*. Avirulent cells similarly grown at 28° are also highly sensitive to phagocytosis (*AV/S*) and retain this sensitivity on similar incubation in broth at 37° (*AV/'R'*).

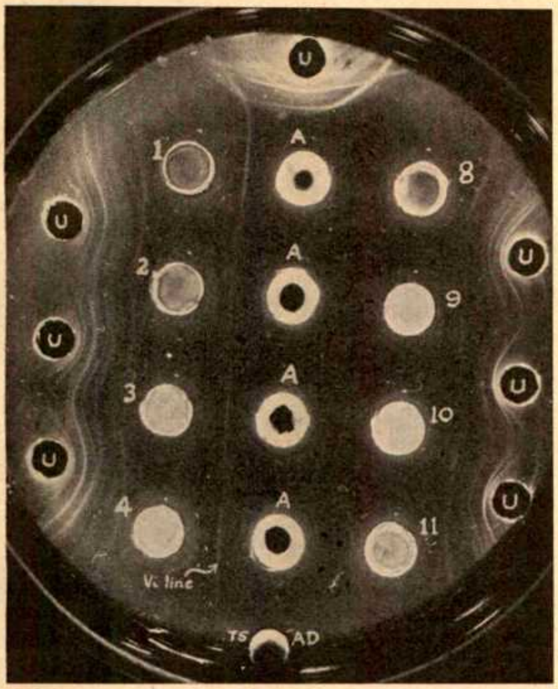

Fig. 1

Reservoirs *A* contain rabbit anti-live *V/R* (strain *MP*6) serum heavily absorbed (100 mgm./ml. serum) with acetone-dried *AV/'R'* (strain *TS*). Reservoirs *U* contain the same serum, unabsorbed.
Reservoirs 1–4 contain virulent organisms in the *V/R* condition (1 strain *MP*6, 2 Yokohama, 3 Shasta, 4 *F*9581).
Reservoirs 8–11 contain avirulent organisms in the *AV/'R'* condition (8 strain *TS*, 9 *A*1122, 10 Soemedang, 11 53*H*1).
Reservoir *TS/AD* contains material as used for absorption

Antisera prepared in rabbits against live *V/R* have the ability to render *V/R* organisms sensitive to phagocytosis when added to a test system *in vitro*. Antisera similarly prepared against *AV/'R'* are poorly able to render *V/R* sensitive under the same conditions. Antisera against both types of organisms contain many antibodies in common, and in similar quantities, and do not differ materially in their content of the important antibody to fraction 1, which, from the studies of Meyer's school[3], plays a major part in protection against virulent infection. Although Englesberg *et al.*[2] consider virulence in strains of *P. pestis* to be intimately connected with the possession of a critical amount of fraction 1 antigen and avirulence to reflect the possession of lesser amounts, I do not think that the resistance of virulent organisms achieved under the above conditions (and hence high virulence) is primarily due to their content of fraction 1.

The evidence for this statement is as follows: The fraction 1 contents of *V/R* and *AV/'R'* as determined by the Ouchterlony[4] technique are similar and very low. *V/R* is not visibly capsulated. *V/R* is poorly agglutinated by high-titre rabbit antisera prepared against highly purified fraction 1 (kindly supplied by Dr. K. F. Meyer). This serum does not render *V/R* sensitive to phagocytosis. Excessive absorption of *V/R* antisera with fraction 1 leaves their ability to render *V/R* sensitive to phagocytosis virtually unaltered. An antigen other than fraction 1, therefore, is responsible for the resistance to phagocytosis shown by *V/R*, and hence, for reasons given earlier, is a determinant of high virulence. As a corollary, all fully virulent strains would be expected to possess this antigen, while avirulent strains may or may not possess it. An avirulent strain possessing this antigen must then owe its avirulent state to the absence of a second determinant of virulence (for example, independence of purine)[5].

Visual evidence for the existence of an antigen differentiating strains capable of resisting phagocytosis, in the absence of visible capsulation, from strains incapable of so doing, is readily obtained by the agar diffusion technique. Fig. 1 gives clear evidence that the fully virulent strains *MP*6, Yokohama, Shasta and *F*9581 contain a diffusible antigen which is not present in detectable amount in the avirulent strains Tjiwidej *S*, *A*1122, Soemedang and 53*H*1. This antigen has been similarly shown to occur in the virulent strain *L*37, the potentially virulent strains *M*1 and *M*7 (Jackson, S., personal communication), and to be undetectable in the avirulent strains Java and 14. It is also to be found in the classical strain *EV* 76, which has frequently been regarded as an avirulent strain possessing a small 'residual' degree of virulence. It is difficult to detect in virulent strains in the *V/S* condition.

Antisera containing antibody specific for this antigen are capable of rendering *V/R* sensitive to phagocytosis. Such antisera retain this capability following heavy absorption with acetone-dried *AV/'R'* but are deprived of it following equal absorption with acetone-dried *V/R*. The antibody response of the mouse towards this antigen appears to be considerably less rapid and intense than that of the rabbit. Experiments to date clearly indicate that specific antigen materially contributes to the passive protective value for mice of antisera produced in rabbits against living *V/R* organisms.

I suggest that, on the evidence presented here, the antigen conferring the important biological property of resistance to phagocytosis and possessed in quantity by all fully virulent strains examined, and undetectable in the majority of avirulent representatives, is a major determinant of virulence in *P. pestis* and represents the long-sought *Vi*-antigen of this organism.

Effects of Anaphylactic Shock and Compound 48/80 on the Mast Cells of the Guinea Pig Lung

Several experiments show a correlation between the number of mast cells in a tissue and its content of histamine[1], and it is possible to obtain histamine from isolated mast granules[2]. Furthermore, alterations of mast cells have been described under conditions in which liberation of histamine occurs in the dog, rat and mouse[3]. We have found that similar changes can be produced in guinea pig lung mast

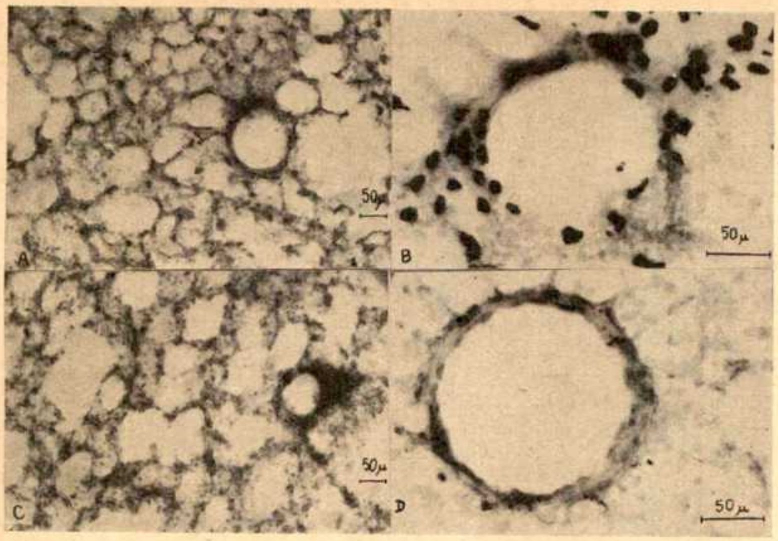

Fig. 1. Frozen sections from guinea pig lung after lead subacetate–ethanol–acetic acid fixation, stained with toluidine blue (pH about 4).

(*A*) and (*B*). Lung from sensitized animal injected with histamine (group II); numerous mast cells in the walls of alveoli and around bronchioles. (*C*) and (*D*). Lung after anaphylactic shock (group I); note reduction in the number of mast cells

cells by means of anaphylactic shock, but not by the action of compound 48/80. Male guinea pigs weighing 300–450 gm. were used throughout. Groups of five animals each were studied. Group I: animals sensitized by injecting 100 mgm. of commercial egg albumin intraperitoneally and 100 mgm. subcutaneously; anaphylactic shock was induced three weeks later by intracardiac injection of 100 mgm. of the antigen in 1 ml. of 0·85 per cent sodium chloride. Group II: sensitized animals killed after shock was induced by intracardiac injection of 200γ of histamine. This group was chosen in order to obtain lungs in similar conditions (emphysematous) to those of group I. Group III: animals injected through the intracardiac route with 0·5 mgm. of compound 48/80. The animals from these three groups were killed by bleeding from the jugular vein when breathing had practically stopped. Group IV: animals killed by a blow on the head and bled from the jugular vein.

The lungs were fixed by injecting a 4 per cent solution of lead subacetate in 50 per cent ethanol plus 0·5 per cent acetic acid through the trachea. Fixation was allowed to proceed overnight, and frozen sections 50μ thick were stained by toluidine blue in acidified solution (pH about 4). The number of mast cells was determined in one hundred randomly chosen 0·1364 mm.[2] areas with the aid of a square-ruled ocular micrometer, the magnification being 250 ×. From the analysis of the counts, the standard error was estimated to be about 7 per cent. Results were studied by variance analysis and the significance of the difference between pairs of means evaluated through the *t* test[4].

In all sensitized animals, the injection of the antigen induced an anaphylactic reaction with death from asphyxia in 3–10 min. Guinea pig lung is rich in mast cells which are present in the walls of the alveoli, around the bronchioles, and concentrated in the pleura. Anaphylactic shock brought out a significant reduction in the number of mast cells (Fig. 1, *A* and *C*, and Table 1), and degranulation and decrease of the metachromasia of the remaining granules in most of the cells (Fig. 1, *B* and *D*). Some mast cells retained their usual morphology. The diminution in the number of recognizable mast cells seemed to be due chiefly to loss of the granules from the cells located in the walls of the alveoli. In one additional group of five sensitized guinea pigs protected with anti-histamine (chlorprophenpyridamine maleate, 5 mgm. for each animal 1 hr. before the injection of the antigen) killed 2 hr. after the injection of the antigen, the mast cells presented the same alterations. Thus, antihistamine is ineffective in protecting mast cells from damage resulting from the specific antigen, seeming rather to act by blocking tissue receptors against free histamine than by preventing the release of histamine.

The injection of compound 48/80 induced a clinical picture similar to that presented by the sensitized animals injected with the antigen. However, no morphological and numerical changes could be found in the mast cells of these animals (Table 1). No significant differences in either number and morphology of the mast cells were found when groups II and IV of control animals were compared. The alterations of guinea pig mast cells in anaphylactic shock were very similar to those observed by Wilander and Jaques and Waters[3] in the dog in peptone and anaphylactic shocks.

The fact that anaphylactic shock produces alterations of the lung mast cells is suggestive of the mast cell origin of the histamine liberated during anaphylactic shock in the guinea pig. Histamine assays have shown that the histamine content of the guinea pig lung is correlated with its mast cell population and that in anaphylactic shock there is a correlated drop in both. It seems that guinea pig mast cells are much more resistant to the action of compound 48/80 than those of the rat. Thus, repeated intraperitoneal injections of compound 48/80, which practically cause the disappearance of mast cells from rat tissues[5], are ineffective in the guinea pig (unpublished results). It is interesting to note that in the guinea pig the release of histamine is not the major toxic action of compound 48/80 [6], and that the histamine-releasing activity of compound 48/80 is very small when its action is studied on the perfused guinea pig lung[7]. A comparative study of the behaviour of the mast cells and the histamine content of guinea pig organs

Table 1. MAST CELL COUNTS IN GUINEA PIG LUNG IN DIFFERENT CONDITIONS

Group	Treatment	Mean counts*	Stand. error	Range
I	Anaphylactic shock	75·3	± 7·7	62–98
II	Sensitized, injected with 200γ histamine	170·1	± 21·0	135–249
III	Injected with 500γ of 48/80	252·1	± 43·8	116–389
IV	Normal animals	255·0	± 32·0	160–334

Labelled Pronuclei in Mouse Eggs fertilized by Labelled Sperm

APPROXIMATELY 38 days after injecting adenine-8-^{14}C into mature male mice, ejaculated sperm showed an autoradiograph in smear preparations[1]. Pronuclei in eggs fertilized by labelled sperm have been examined for autoradiographs.

Fallopian tubes from a superovulated female, killed approximately 12 hr. after mating to one of these males, were fixed in Bouin. They were sectioned at 10µ, bleached in lithium carbonate, and coated with Kodak stripping film. The sections were stained with celestine blue and studied under a phase-contrast microscope.

Of twelve eggs examined, eleven had two pronuclei, and one had three pronuclei. In each bipronucleate egg one pronucleus showed an autoradiograph, and was assumed to be male. The unlabelled pronucleus was nearer the second polar body in six out of seven eggs in which the distance could be estimated; this agrees with the morphological evidence of the proximity of the female pronucleus to the second polar body. A possible autoradiograph on the vitellus of some eggs was perhaps related with the path of entry of the sperm. Spermatozoa in the perivitelline space, in the lumen of the tubes, and in the cumulus showed distinct autoradiographs.

In the tripronucleate egg, two pronuclei showed autoradiographs. The egg was presumably dispermic. The labelled pronuclei were larger than the third, and the second polar body had been extruded; this evidence supports the postulate of dispermy[2].

Calculation from data of total incorporation of the tracer in sperm[1] shows that for a pronucleus with diameter 20µ, sectioned at 10µ, and assuming all the tracer from the sperm to be present in the pronucleus and evenly distributed, the maximum density of the autoradiograph could be approximately $0{\cdot}2 \times 10^7$ grains/cm.^{2}. This value is at the limit for recognition[3]. But usually the tracer is concentrated in certain parts of the pronucleus, and this gives a more contrasted autoradiograph which can be clearly recognized.

Conversion of Phenylalanine into Tyrosine in the Silkworm Larva (*Bombyx mori*)

IN silkworms, it has been found that tyrosine is used not only for biosynthesis of the silk proteins[1], but also to form melanin pigments, but little is known of its origin. The present work was carried out, using phenylalanine labelled with carbon-14, to examine whether phenylalanine is a precursor of tyrosine.

Radioactive L-phenylalanine,

(0·84 mc. per m.mol.), was obtained from the Radiochemical Centre. 0·5 µc. of radioactive phenylalanine (99 µgm. as amino-acid) per worm was injected into the body cavity of the silkworms, *Si* 122 × *Nichi* 122♂, at the fourth day of the fifth instar. Following the injection, these silkworms continued to feed normally for 72 hr. and then they began spinning their cocoons. Specific activity of the cocoon fibres measured with an *SC*-16 windowless gas-flow counter (Tracerlab Inc.) was 4·154 c./min./100 mgm. (average). 4·86 gm. of the radioactive cocoon fibres was cut into small pieces and degummed by boiling with distilled water and *M*/50 sodium carbonate solution repeatedly, until the weight of fibroin became constant. The fibroin was washed with ethanol and ether, and dried; the yield was 3·47 gm. 3·47 gm. of fibroin was hydrolysed with concentrated hydrochloric acid as usual. Tyrosine was isolated directly from the hydrolysate according to the procedure of Abderhalden[2]. From the filtrate from which tyrosine had been removed, glycine was removed as a salt of 5-nitro-naphthalene-1-sulphonic acid, and then alanine as azobenzene *p*-sulphonate, and these amino-acids were separated from their respective salts[3]. Tyrosine was recrystallized from hot water, and glycine and alanine from water by adding absolute ethanol repeatedly until their specific activities became constant.

Radioactivities of the amino-acids isolated from fibroin are summarized in Table 1. Almost all the activity was located in tyrosine.

Isolated tyrosine was analysed by paper chromatography, using phenol containing 0·1 per cent ammonia as a solvent. The strip was sprayed with ninhydrin in the usual way, the position of tyrosine

Table 1. RADIOACTIVITIES OF THE AMINO-ACIDS ISOLATED FROM FIBROIN

Amino-acids isolated	Specific activity	Yield from 3·47 gm. of fibroin (mgm.)
Tyrosine	41·147 c./min./mM	194
Glycine	26 ,,	101
Alanine	50 ,,	145

marked and the strip scanned for radioactivity by an *SC*-16 windowless gas-flow counter (Fig. 1). As shown in Fig. 1, high radioactivity was recognized at the position of tyrosine. A radioautograph obtained by superposition of an X-ray film on the chromatogram of isolated tyrosine at 1° for two weeks gave also an image at the position of tyrosine. These results seem to suggest that the tyrosine isolated is labelled with isotopic carbon.

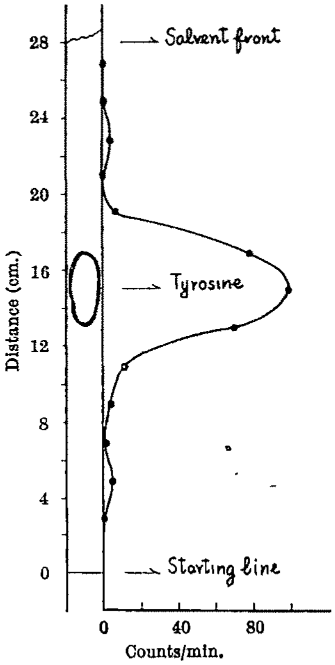

Fig. 1. Radioactivity of chromatogram of isolated tyrosine. Phenol run from starting line

In view of the high tyrosine content of the cocoon fibres, Holtzmann[4] compared quantitatively the tyrosine intake of the silkworms with that of the cocoon fibres produced, and suggested that the mulberry leaves contained so much tyrosine that there was no need to suppose that the silkworm synthesized tyrosine. Recently J. Kirimura (unpublished work) carried out the same experiment, using the microbiological method instead of Folin and Marenzi's method adopted by Holtzmann for the assay of tyrosine, and claimed that tyrosine was synthesized *in vivo*. The present work confirms that tyrosine is synthesized from phenylalanine *in vivo*, and then is utilized for biosynthesis of the silk proteins.

Raper[5], Mason[6] and others have suggested that melanin pigments are derived from tyrosine. Since the present work shows that tyrosine originates from phenylalanine in the silkworm, the mechanism of formation of melanin pigments in insects may be as follows :

Phenylalanine → tyrosine → dopa → dopaquinone → leucodopachrome → dopachrome → 5,6-dihydroxyindole → indole-5,6-quinone → melanin.

Effect of Cortisone on the Reticulo-Endothelial System

PATIENTS undergoing cortisone treatment are very liable to intercurrent infection[1]. Further, it has been established by animal experimentation that cortisone enhances all the common bacterial infections[2], including those with spirochætes[3] and the tubercle bacillus[4].

Preliminary investigations by Nicol and Snell[5] showed that, in the guinea pig, cortisone depresses the activity of the reticulo-endothelial macrophages especially in the spleen, and suggested that this was the manner in which the defences of the body are lowered against infection and new growth. These researches have now been extended, using different doses of cortisone and continuing the treatment for a longer period, and the results are recorded in the present communication.

Seventy-nine male guinea pigs aged about one year were used for the investigation. The reticulo-endothelial macrophages were studied by giving all the animals one daily injection of trypan blue subcutaneously for the last six days prior to being killed by chloroform. The dosage of the dye was calculated on the basis of 0·8 ml. of a 1 per cent solution in distilled water per 100 gm. body-weight. Seven of the animals were given dye only and were used as controls. The remaining seventy-two animals were divided into twelve groups each of which received 5, 10 or 25 mgm. of cortisone intramuscularly once daily for a period of 1, 2, 3 or 4 weeks in addition to the dye. Specimens were taken from the spleen, liver and lymph nodes and fixed in Heidenhain's 'Susa' fluid. Sections were cut at 10μ thick and stained with weak eosin, dilute carbol fuchsin or alum carmine. The activity of the reticulo-endothelial system in the organs studied was assessed by the number of dye-bearing cells present and the intensity of the vital staining.

In the animals which received cortisone treatment for one or two weeks, the intensity of the vital staining was markedly reduced in the macrophages of the spleen, liver and lymph nodes compared with the appearances in the controls. At the same time the mortality was high and the lymph nodes became atrophied. This depressant effect showed itself earlier in the animals which received the larger doses of cortisone. Post-mortem examination of the animals which died suggested that death had occurred as the result of the reticulo-endothelial system becoming depressed and unable to detoxicate the trypan blue.

In the animals which received cortisone for three or four weeks, the intensity of the vital staining was practically similar to that of the controls, the mortality was low and the lymph nodes were hypertrophied.

The above results show that the reticulo-endothelial system becomes markedly depressed during the first two weeks of cortisone treatment, then recovers to about the normal level during the third and fourth weeks. This suggests that patients should be specially protected from intercurrent infection during the early stages of cortisone therapy.

Factors influencing the Transport of Sea Water Cations across the Ectoderm of *Fundulus heteroclitus*

In 1913 George G. Scott reviewed the then existing literature and added experiments of his own on the remarkable ability of adult *Fundulus heteroclitus* to withstand wide variations in the osmotic pressure of their environment[1]. The significance of his conclusions is retold in the easily observed hardiness of these teleosts. The survivors of such changes appear to function adequately to gross observations. Similarly the *Fundulus* embryos, although less than 2 mm. in diameter, and with tissues that are readily torn with sharp glass needles, will develop in extremes of distilled water and sea water with salts or sucrose added up to twice the normal osmotic pressure.

Following closure of the blastopore, the *Fundulus* embryo is essentially two compartments. The first is the yolk, which is entirely surrounded by the second, the embryo proper. This latter is not really homogeneous, for it consists of the syncytial periblast, in direct contact with the yolk, and the developing organs of the embryonic axis, as well as the ectoderm, which is the only tissue in contact with the surrounding medium. When Oppenheimer stages 22–26 are used[2], there are no orifices present, such as gill slits, or cloaca, so it will be seen that a single membrane is presented to the external environment, and that the yolk compartment is totally surrounded. The changes in the cationic content of these two compartments are therefore functions of the permeability of the ectodermal membrane.

Studies of this permeability consisted of artificial media containing each of the cations sodium, magnesium, potassium, and calcium in the same concentrations as in sea water, and combining them in twos and threes, and singly as well as all four together. The chlorides were used throughout. Each medium was studied with sucrose to balance the osmotic pressure to that of sea water as well as without the sucrose. Radiotracer sodium, calcium and potassium were used. Magnesium was studied by photometric microchemical analysis. Total cellular sodium and potassium were estimated by flame photometry, while total calcium was estimated by a photochemical technique using ethylenediaminetetraacetate. The uptake and loss of ions under the influence of 0·05 *M* fluoride and 0·001 *M* iodoacetate were studied.

The uptake curves were essentially linear with a decrease in the slope near equilibration. Fluoride changed only the slope, but not the linearity, except for sodium, which developed a biphasic curve. Loss of ions into media lacking them also followed a linear pattern. Fluoride again changed the slope but not the linearity.

When the effects of presence and absence of ions were considered, several patterns appeared. When magnesium and potassium were combined, the result was always an increased gain in magnesium and inhibition of potassium. Calcium and sodium were mutually antagonistic, as were calcium and the two other ions. The change in osmotic pressure gained by removal of sucrose profoundly altered many ion balances.

The position of the yolk requires that any ions entering or leaving it must pass across the dual membrane that surrounds it. The inner half of this is the syncytial periblast. Parpart, in a discussion of a paper by Sheppard and Stewart[3], raises the pertinent question as to just where in the cell is the potassium (and for that matter, the other ions as well). In an epithelial layer, if the ions existed and moved in the plasma membrane complex of the individual cells, then they could travel across a cellular membrane by passage in some manner along the cell membranes that run vertically in the epithelium. No such 'passage-ways' exist across the periblast. Radiotracer sodium, calcium, and potassium have been recovered from, and observed to pass out of, the yolk of *Fundulus* embryos. The results failed to indicate whether magnesium did the same. Unless some specific mechanism can be demonstrated, such as fragmentation of the plasma membranes or intermittent functional contact between opposite layers, this represents evidence that ions pass in some fashion through the medullary cytoplasm of cells.

Studies with the fluoride ion suggest that a glycolytic mechanism provides energy for the transport of ions both into and out of the cell. Patterns of inhibition and facilitation suggest that to some extent places on a transport mechanism are nonspecific.

The internal colloid pressure of these eggs is about 20–25 per cent of the surrounding sea water, and some mechanism may be active to maintain this. Indirect evidence from these studies suggests that part of the water may be under the influence of glycolysis. Each of the partial media is hypotonic to sea water and should dilute the egg contents. In some examples, however, concentration occurs. Based on this indirect observation, fluoride added to sodium balance in the presence of a constant osmotic pressure (from sucrose) showed a marked increase in the intracellular sodium, which is opposite to both the effect of fluoride by itself and the change that comes from adding sucrose to maintain the external colloid pressure. The time course was two-and-a-quarter hours, or insufficient time to lose significantly other intracellular ions in the presence of fluoride. This is interpreted as fluoride interfering with mechanisms which normally carry water into the egg, the loss being a manifestation of the markedly higher external colloid pressure. That the egg may indeed have some control is further shown by reducing the external osmotic pressure to about 75 per cent of its normal value, at which point the influence of 0·05 *M* fluoride in this time interval is essentially none on the same situation. The effect of higher concentrations of fluoride has not been studied.

Organic Binding of Iodine in the Endostyle of *Ciona intestinalis*

It has very commonly been supposed that the endostyle of the Protochordata is homologous with that of the ammocœte larva and is thus the forerunner of the thyroid gland, which is well known to develop from the ammocœte's endostyle when this animal metamorphoses into the adult lamprey. This interpretation has, however, come under criticism as a result of recent investigations which have established the existence of thyroidal function in the endostyle of the ammocœte[1,2], but have failed to demonstrate any organic binding of iodine in the endostyle of the Tunicata, although this has been shown to occur in the stolonic septum of *Perophora annectens*[3]. These findings have been held to indicate that the endostyle "may not be the homologue of the thyroid"[3], and that "it is probably unfortunate that the elongated subpharyngeal glandular sac of cyclostome larvae . . . has come to be known as 'endostyle' "[4].

This uncertainty of interpretation has led us, in the course of a study of endostylar function in the ammocœte, to examine the situation also in *Ciona intestinalis*. The existence of iodine in the ascidian test has long been known[5], but we are now able to report that autoradiographs of *Ciona*, prepared by the stripping-film technique, clearly demonstrate the presence of bound iodine both in the epithelial cells at the base of the test and also in the endostyle. In the latter organ it is found in a well-defined zone of non-ciliated epithelium which lies along the medial sides of the lips of the endostylar groove; this zone lies dorsal to, and is quite distinct from, the glandular tracts which provide the secretion utilized in the feeding mechanism. A dense deposit of iodine is also associated with an equally well-defined zone of ciliated epithelium which forms the summit of the lips, and which is said to sweep the endostylar secretion out of the groove and on to the lateral walls of the pharynx, where it aids in entangling the food particles[6]. It thus seems probable that the iodinated product must become mixed with the food and transferred to the intestine, and in agreement with this we do, in fact, find iodinated material on the wall of the pharynx and in the intestinal contents.

The association of thyroidal products with the bound iodine in the endostyle of *Ciona* is still to be established, although it is rendered highly probable by the known existence of thyroxine or its precursors in the epithelial or skeletal tissues of invertebrates as diverse as cœlenterates, annelids and molluscs[4,7]. It has been plausibly argued[4] that such iodinated amino-acids might often have been formed 'accidentally', and that the thyroid gland might have arisen in the Chordata in consequence of these compounds becoming directly involved in metabolism, with the resulting need for localization and specialization of the source of iodoprotein. From our study of the ammocœte's endostyle we had already concluded that the organization of its epithelium could best be understood on the view that it comprised two distinct types of secretory process, one alimentary (in the general sense of being concerned in the feeding mechanism) and the other thyroidal, and even on the present limited evidence the similarity between this situation and that in *Ciona* is striking enough to suggest that the first steps in the evolution of thyroidal function may already have been initiated in the protochordate endostyle. In this connexion it may be significant that secretory inclusions which are positive to the periodic-acid–Schiff test are conspicuous in the non-ciliated iodine-binding cells of the endostyle of *Ciona*, for we have also found characteristic inclusions positive for the periodic-acid–Schiff test in the thyroidal cells of the ammocœte's endostyle and believe that these may well be homologous with thyroid colloid.

These investigations are continuing, but the facts at present available appear to us to offer the strongest support for the interpretation of the protochordate endostyle as the homologue of the thyroid gland, and for the old-established view that the history of the latter "has been one in the course of which a feeding structure has been transformed into a gland of internal secretion"[8]. They carry also the implication that the characteristic features of thyroidal function may eventually prove to have been established much earlier in the chordate line than has previously been suspected.

Examples of Anti-competitive Inhibition

Anti-competitive (uncompetitive) inhibition, in which the inhibitor combines with the enzyme-substrate complex but not with the enzyme, has been considered theoretically by Burk in Ebersole, Guttentag and Wilson[1].

The kinetic equation for this type of inhibition is

$$\frac{1}{v_i} = \left(1 + \frac{[I]}{K_i}\right)\frac{1}{V^0} + \frac{K_s}{V^0}\,\frac{1}{[S]}$$

where v_i is the velocity of the enzymatic reaction at substrate concentration $[S]$ in the presence of inhibitor concentration $[I]$, V^0 is the maximum velocity in the presence of inhibitor and K_i and K_s are the inhibitor and equilibrium constants respectively. If anti-competitive inhibition occurs, the plots of $1/v_i$ against $[I]$ at different substrate concentrations, or

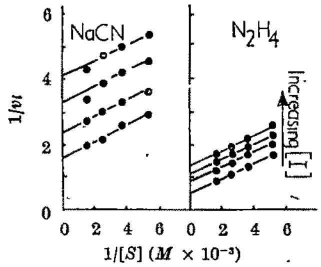

Fig. 1. Relation between $1/v_i$ and $1/[S]$ for the arylsulphatase of *Alcaligenes* using four different concentrations ($6·25 \times 10^{-3}$, $12·5 \times 10^{-3}$, $18·7 \times 10^{-3}$ and 25×10^{-3} *M* sodium cyanide or hydrazine) of inhibitor

$1/v_i$ against $1/[S]$ at different values of $[I]$, yield families of parallel lines[1,2].

Known cases of this type of inhibition are rare. An example is afforded by the combination of azide with the oxidized form of the *Atmungsferment*[3], and it seems to us that the inhibition of pepsin with hydrazine[4] provides a second example. Two further examples have now been obtained during investigations of the inhibition of the arylsulphatase of *Alcaligenes metalcaligenes*. Using *p*-nitrophenyl sulphate as substrate, the plots of $1/v_i$ against $[I]$ or $1/v_i$ against $1/[S]$ for the two inhibitors, sodium cyanide and hydrazine hydrochloride, gave families of parallel lines, an example of which is shown in Fig. 1.

An examination of the variation of K_m with change in *p*H had indicated that the complex arising from the combination of this arylsulphatase and *p*-nitrophenyl sulphate contains a dissociating group (*pK* at *p*H 7·9) which is not present in the enzyme alone[5], and this may be the group which reacts with cyanide and hydrazine. Moreover, the degree of inhibition of the enzyme caused by cyanide and hydrazine varies with *p*H and increases sharply above the region of *p*H 7·9.

The inhibition of other arylsulphatases by carbonyl reagents, such as cyanide and hydrazine, has been previously noted[6-8], and it has been suggested by Rosenfeld and Ruchelman[6], for the arylsulphatase of takadiastase, that the enzyme contains aldehydic groups which are essential for activity. If, on further examination, these cases of inhibition also prove to be anti-competitive, then the views of Rosenfeld and Ruchelman would need to be modified, since the inhibitor-coupling group would not be present *in esse* in the enzyme.

Avidity of the Tetracyclines for the Cations of Metals

THE high affinity of chlorotetracycline (aureomycin) and oxytetracycline (terramycin) for the cations of heavy metals has been reported[1]. This investigation is now extended to the parent substance, tetracycline, with the results shown in Table 1, which also includes some new values for the substituted tetracyclines.

Ionization Constants. Tetracycline hydrochloride, dried for an hour in air at 110°, was dissolved (0·001 *M*) in boiled-out water and titrated potentiometrically under nitrogen with three equivalents of 0·1 *N* potassium hydroxide added in thirty equal portions. This gave the three ionization constants: 3·35 (basic), 7·82 and 9·57 (all within ± 0·06). The two acidic constants, being close together, were separated by Noyes's method[2]. Consideration of inductive effects indicates that these constants belong to the 2-, 5- and 7-positions respectively because they are all higher (up to 0·4 unit) than those of chlorotetracycline, which are higher than those of oxytetracycline[1].

Stability Constants. One half atom of a di- (and one third of a tri-) valent metal per molecule of chelating substance was added as a salt to a fresh portion of solution which was titrated as above (two equivalents of alkali only). Aluminium was introduced as alum, and ferric iron as the nitrate recrystallized from dilute nitric acid, dissolved, adjusted to *p*H 2 and standardized (this prevented interference by the bisulphate ion previously encountered with ferric ammonium sulphate[1]). For determination of log K' of ferric ion, the solution had to be back-titrated with *N* nitric acid (7 equiv.). Formation curves showed good inflexion between the steps of complex-formation[3], and hence the appropriate calculations were those used for the simpler amino-acids[4]. Foaming was observed as before[1].

It is seen from Table 1 that the stability constants of tetracycline are similar to those of its chloro- and hydroxy-derivatives[1]: the overall ferric value (K_s), however, is exceptional in being 1,260 times greater. The affinity of the three tetracyclines for divalent cations is of the same order as those of the common amino-acids[4] which do not combine appreciably with ferric ion.

It is not yet known if the antibacterial action of the tetracyclines is connected with their metal-

Table 1. STABILITY CONSTANTS FOR THE METAL COMPLEXES OF THE TETRACYCLINES

Cation	Log K' (1 : 1-complex)	log K'' (2 : 1-complex)	log K_s (overall)	Colour of complexes
	Tetracycline			
Fe^{3+}	9·9	8·6	25·3[b]	Red
Al^{3+}	7·4	6·4	19·2[e]	Yellow
Cu^{2+}	7·8	5·0	12·8	Green
Ni^{2+}	6·0	5·0	11·0	Green
Fe^{2+}	5·3	4·0[a]	9·3	Red
Co^{2+}	5·4	4·4	9·8	Yellow
Zn^{2+}	4·9	ppt	(9)[f]	Yellow
Mn^{2+}	4·4	ppt	(8)[f]	Yellow
	Chlorotetracycline			
Fe^{3+}	9·4	7·2	22·2[c]	Red
Al^{3+}	7·2	ppt	(18)[f]	Yellow
Ni^{2+}	5·8	4·7[a]	10·5	Green
	Oxytetracycline			
Fe^{3+}	9·6	7·2	22·5[d]	Red
Al^{3+}	7·0	ppt	(18)[f]	Yellow
Mg^{2+}	3·8	—	—	Green

(*a*) Precipitation prevented direct determination. Hence log K'' was obtained by subtracting log K' from log K_s (which was found at $\bar{n} = 1$).

(*b*), (*c*), (*d*), (*e*). These values include a log K''' of 6·8, 5·6, 5·7, and 5·4 respectively.

(*f*) Deduced values (approx.).

binding powers, as that of 8-hydroxyquinoline is[5]. Dr. A. J. Tomlinson, who has kindly compared these substances on *Staphylococcus aureus*, reports that the tetracyclines kill much more slowly than 8-hydroxyquinoline and, unlike the latter, are highly active in iron-depleted media. In any event, knowledge of the metal-binding properties of these drugs is valuable because in the human body they cannot fail to combine with metallic cations. Model experiments[6] have shown that the practice of giving alumina with the tetracyclines (to prevent gastric irritation) completely inactivates them, as the constants given here would suggest.

We thank Dr. B. L. Hutchings of Lederle Laboratories for the chemically pure tetracycline.

Stabilized Interference Fringes on the Retina

A method of producing a stabilized retinal image (that is, an image which is stationary on the retina) was first described in *Nature*[1], and other work has been reported elsewhere[2-4]. Here we describe a method of producing a stabilized image with interference fringes. A cylindrical unit 6 mm. in diameter and 3 mm. thick is formed by cementing a calcite crystal between two pieces of 'Polaroid'. This unit is cemented to a steel ball which fits tightly into a ball-socket joint on a stalk fixed to a contact lens as shown in Fig. 1.

If convergent light is incident as shown, the subject wearing the contact lens sees a pattern of rings and brushes when the eye is focused for infinity. The centre of the pattern is in the direction of the optic axis of the calcite and the image on the retina is stabilized provided that this axis is fixed relative to the optic axis of the eye. It has been previously shown[5,6] that a well-fitting contact lens follows small eye movements very accurately.

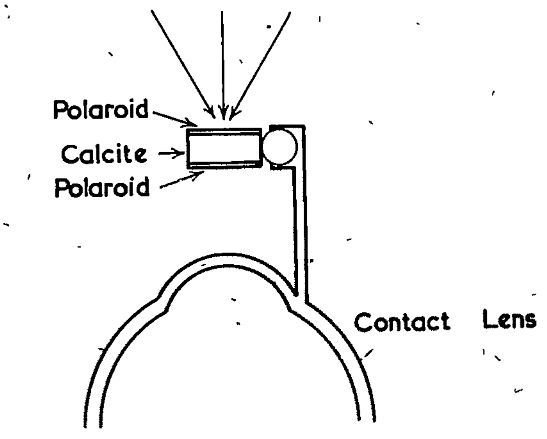

Fig. 1

When the subject first looks at a suitable source, the fringes are clearly seen but they fade in a period of 1–5 sec., leaving a grey field which sometimes goes black. This fade-out persists for about 10 sec., after which the eye makes a sharp and uncontrollable movement and the fringes are again seen very clearly. Sometimes the fringes reappear much less clearly and over only a part of the field without any violent movement of the eye. The fade-out has been observed at the very high brightness obtained by allowing the subject to view a bright cloud through the unit. With light interrupted at a suitable frequency the image does not fade out.

Other ways of producing stabilized fringe systems on the retina are being investigated. A sharp fringe pattern has been obtained by substituting a small Fabry–Perot étalon for the 'Polaroid'–calcite unit and the fade-out has been observed with this arrangement.

The method here reported is not suitable for certain types of experiment which can be carried out with the apparatus previously described[3], but for some experiments it has considerable advantages of simplicity and convenience.

This work is assisted by a grant from the Medical Research Council.

Bombardment of Glass by Alpha-particles

In the course of work previously carried out elsewhere, the production of a solid amorphous deposit in soda-glass vessels containing solutions of radium salts was observed; visible quantities were produced, for example, in six months by a solution containing 3 mgm. of radium (as chloride) in 25 ml. of solution. Recently, further investigations have been undertaken on this effect, which is attributed to the physico-chemical breakdown of the surface of the glass following α-particle bombardment.

The solid formed by the action of strongly α-active solutions upon glass is of an amorphous flocculent nature and off-white in colour. After thorough washing, spectroscopic analysis of a typical sample showed silicon as the only major constituent. The solid is strongly adsorbent. Irradiation of glass by a 30-curie cobalt-60 source to give absorption of a γ-ray flux comparable to the α-particle energy deposited, followed by prolonged digestion with water on a steam-bath, did not bring about any formation of solid material in the digesting liquid.

In the present experiments, radon was used as a source of α-particles. Irradiations were carried out in the presence and absence of water; subsequent digestion at 80° C. with dilute acid produced solid deposits in both cases. To the naked eye, these products appeared to be of different types, in that that from the dry-way irradiation appeared to be in the form of minute plates, whereas irradiation in the presence of water produced the amorphous solid previously observed. X-ray diffraction photographs, however, showed that both solids were amorphous.

The leaching of soda-glass and 'Pyrex' samples irradiated in the dry state has been followed by measuring the build-up of 'soluble' silica in the aqueous phase. Analysis was carried out by measuring absorptiometrically the colour produced by the reduction of the silico-molybdic acid complex with ascorbic acid (Gibson, unpublished work at Harwell). Fig. 1 shows the results for soda-glass samples. After the initial attack, complete in about seven hours for irradiated soda-glass and in about twelve hours for 'Pyrex', leaching takes place at a steady rate which is characteristic of the original material. The effect of α-particle dose is clearly shown. Soda-glass yields approximately ten times more silica than 'Pyrex', for equal intensity of irradiation. There was no detectable difference in the small quantities of sodium leached from normal and irradiated soda-glass.

Slight changes in density have been observed in both 'Pyrex' and soda-glass after α-particle bombardment.

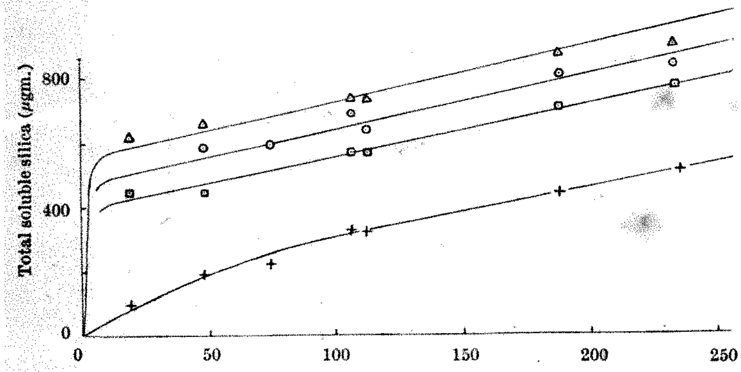

Fig. 1. Leaching of silica from irradiated soda glass: ⊡—⊡—, 10^{14} α-particles/cm.^{2}; ⊙—⊙—, 2×10^{14} α-particles/cm.^{2}; △—△—, 3×10^{14} α-particles/cm.^{2}; +—+—, unirradiated sample

The overall α-particle dose absorbed by the glass is smaller than that predicted by Seitz[1] as necessary to cause significant changes in the physical properties of a solid. A microscopic study of the surface of the irradiated specimens has been carried out by Mr. D. R. Knowles (U.K. Atomic Energy Authority (I.G.), Culcheth, Lancashire; private communication), whose assistance is gratefully acknowledged. This reveals small localized areas of affected surface on the irradiated specimens, suggesting that non-uniform α-bombardment may have occurred. This work, and that on other aspects of the problem, are continuing; it is hoped to publish a fuller account elsewhere.

Heat Convection from the Earth's Surface

Evidence has been presented[1] which suggests quite strongly that a regime of effectively free convection of heat begins to operate in the surface layers of the atmosphere at a negative Richardson number as low as 0·02 or 0·03. It is improbable that this can take the form of regular cellular convection of the type studied by Rayleigh and recently elaborated by Malkus[2], for this would require in a layer of depth h that

$$\frac{-\frac{g}{\theta}\frac{\partial\theta}{\partial z}h^4}{\kappa\nu} > 1{,}100 \text{ at least,}$$

the symbols having their usual significance. If we replace κ and ν by their turbulent counterparts

$$K_H \approx K_M \approx k^2z^2\left(\frac{\partial u}{\partial z}\right)$$

and average through the depth of the layer, then

$$\overline{K_H} \approx \overline{K_M} \approx \alpha k^2h^2\,\overline{\frac{\partial u}{\partial z}}$$

where α is less than but comparable with unity. This transforms the Rayleigh criterion into a Richardson criterion

$$\frac{-\frac{g}{\theta}\frac{\partial\theta}{\partial z}}{\left(\frac{\partial u}{\partial z}\right)^2} = -Ri > 28\,\alpha^2$$

When there is some wind and wind shear, therefore, cellular convection should not set in until $-Ri$ exceeds a value of order 1–10, whereas the free-convection regime in fact effectively sets in at a very much smaller value.

By considering the dynamics of convection in isolated columns in a thermally stratified environment, it may be shown, from the equations formulated by Priestley and Ball[3], that the heat flux brought about by spontaneously generated columnar convection may exceed that due to forced convection provided that $-Ri > 0·035$. If we now consider these columns as drawn out by the wind into vertical planes, from which heat and vertical momentum are lost by diffusion in only one horizontal dimension rather than two, the free convection at a given lapse-rate would be yet stronger; convection in this form can exceed the forced convection when $-Ri > 0·011$. There is therefore reason in theory to expect free convection to begin to operate at quite small Richardson numbers, and to take initially the planar form with orientation downwind, with an increasing proportion of columnar forms as $-Ri$ increases. A number of other lines of evidence (see, for example, ref. 4) support the appropriateness of this picture.

There is a limit to the rate at which Nature requires heat to be carried away from the surface. Since the columnar and planar forms of convection appear capable of disposing of the heat at sufficient rate, the very strong temperature gradients required for the onset of cellular convection of the Rayleigh type will not in general be realized.

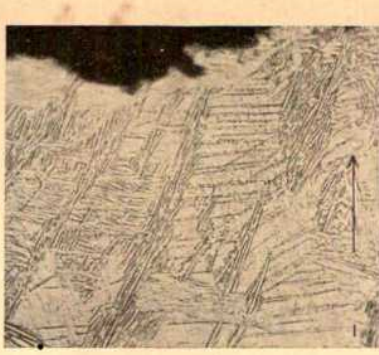

Fig. 1. Mechanical twinning near the fracture in tensile specimen of *RC*-130*B* titanium alloy. × 250

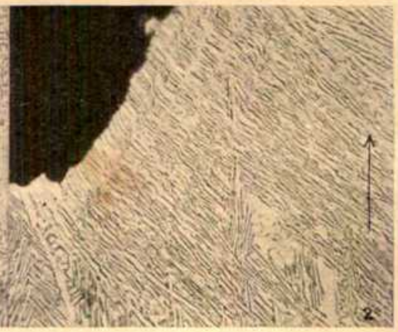

Fig. 2. Steplike twin structure near fracture in tensile specimen of *RC*-130*B* titanium alloy. × 250. Arrows show direction of tensile stress

Measurements of heat flux[5] have indicated[1] that the complete transition from forced to free convection may take place much more sharply than had previously been supposed. This is thought to be a manifestation of the tendency of the temperature profile to adjust itself to the heat flux, and in particular to adopt a form which permits a constancy of heat flux with height. From the dynamics of the columnar and planar forms of convection, it can be shown that, assuming the profile to be of the form

$$\frac{\partial\theta}{\partial z} \propto z^{-\delta}$$

the constancy of heat flux is satisfied when $\delta = 1$ and forced convection dominates, and when $\delta = 4/3$ and free convection dominates, but not in the intermediate state when both mechanisms are operative. Close to the ground will be a layer where forced convection is dominant, provided some wind is blowing. But above the level at which the effects of free convection first begin to be felt, there will be a strong adjustment bias towards the 4/3 power law which allows free convection to dominate. Under ideal conditions of test, that is, when lag and advective effects are negligible, the intermediate state should occupy only a rather narrow range of levels (under given conditions) or of conditions (at a given level) and would tend to be transient. A fuller account of this work is in preparation.

Metallographic Evidence of Mechanical Twinning in an Alpha-Beta Titanium Alloy

As part of an investigation of the response of titanium alloys to heat treatment, longitudinal metallographic sections were prepared through the fracture region of broken tensile specimens. Metallographic examination of the tensile fractures of commercial titanium–aluminium–manganese (92–4–4) alloy (*C*-130*AM*), heat-treated to produce acicular alpha in a beta matrix, has resulted in the discovery of structures tentatively identified as mechanical twins.

An example of the appearance of the twinned structure is shown in Fig. 1. The twinned orientation is confined to the close-packed hexagonal alpha phase, but appears to pass unhindered through the intervening body-centred cubic beta phase, so that each twin can be followed across several adjacent alpha needles. No evidence of twinning is visible in the beta phase, indicating that the twinning distortion is carried through the beta phase by a slip process.

Another example of twinning in this alloy is shown in Fig. 2. A large movement of the alpha needles is evident, forming a pronounced steplike structure. It is improbable that this amount of distortion could be developed during polishing. Therefore it is concluded that twinning occurs normally during the deformation process.

Twins thus far observed have tended to be quite broad and to be lens-shaped in appearance. This appearance has been shown by Rosi *et al.*[1] to be typical of $\{10\bar{1}2\}$ type twins in alpha-titanium.

The two structures shown were obtained during examination of standard 1-in. gauge-length round tensile specimens broken with a platen speed of 0·01 in. per min. Total elongation before fracture was approximately 8 per cent. These specimens had been heat-treated to produce a fine acicular alpha structure in a continuous beta matrix by heating into the all-beta field and cooling at a rate sufficiently slow to promote the nucleation and growth of the acicular alpha structure. With this heat treatment, the coarseness of the alpha needles can be controlled to a considerable extent by controlling the rate of cooling through the beta-to-alpha transformation.

Twinning has also been observed in specimens heat-treated to produce considerably coarser alpha needles; but, in these cases, the extent of twinning was much less. Twinning was generally most prominent in the region of fracture; but occasional isolated regions showing twinning have been observed at considerable distances from the fracture.

If X-ray examination confirms these structures to be true mechanical twins, the observation that twinning can be propagated across intervening non-twinning material without loss of continuity of the twin boundary should prove of assistance in developing a suitable theory of the twinning process.

This research was carried out as part of an investigation of the heat treatment of titanium alloys, sponsored by the Aircraft Gas Turbine Division of the General Electric Company. Permission to publish these results is gratefully acknowledged.

Additional Records of *Haplosporangium parvum* in Mammals in Britain

THE presence of a pulmonary fungus, *Haplosporangium parvum* Emmons and Ashburn[1], has been reported recently by McDiarmid and Austwick[2] in moles, *Talpa europaea*, in England. The identity of large spherules, 100–390 microns in diameter, found in the lungs was confirmed by culture. These findings are of particular interest to me as they help solve a parasitological enigma encountered in Britain in 1945.

While on military duty in England, I examined a considerable number of small mammals which I trapped between October 22, 1944, and March 5, 1945, on the chalk downs near Camp Blandford, two miles north-east of Blandford, Dorset. The lungs of some of these mammals contained hard, discrete spherules ranging up to 250 microns in diameter. Each spherule, which was visible to the naked eye, could be removed easily with forceps. It appeared to have two walls and was filled with 'cells' resembling oil globules. When pressure was applied, it cracked audibly. In a few specimens the lung tissue surrounding a spherule was cloudy in appearance, possibly fibrotic. Some animals were infested with a large number of the cyst-like objects.

Notes made at the time (January 17, 1945) read as follows: "Today I saw Dr. H. A. Baylis of the British Museum to whom I had sent parasitic worms for identification. He is particularly interested in the cysts from the lungs of *Clethrionomys*. He cannot determine what causes them. He expected to find trematode larvæ within but was unable to demonstrate such. According to him, the interior of a cyst is composed of nothing but oil globules; therefore, when a cyst is sectioned for microscopic examination it appears to be empty. Lungs which Baylis cleared show how evenly and thickly the cysts are distributed through the tissue. As an alternative to trematode larvæ, Baylis thought the cysts might have been caused by mites or pollen grains. In favour of the mite theory he had noted in some instances a suggestion of spines within a cyst. However, the hard shell is composed of two layers: an outer one formed by the lung tissue and an inner one presumably formed by something within the cyst".

This experience closely parallels that of American workers when the large form of *Haplosporangium* was encountered and described as an undetermined parasite[3].

I have since become familiar with *Haplosporangium* in North American rodents and am certain that the spherules observed in the lungs of rodents in England are the same. The work of McDiarmid and Austwick (*l.c.*) tends to confirm this identification. The lung specimens from Camp Blandford were left with Dr. Baylis. In reply to a recent inquiry, officials of the British Museum stated that Dr. Baylis had retired and the specimens could not be readily found.

Mammals examined and infections detected at Camp Blandford were as follows: *Apodemus sylvaticus*, sixty (one infected); *Apodemus flavicollis*, three (one infected); *Clethrionomys glareolus*, thirty-eight (nine infected); *Sorex araneus*, thirteen; *Sorex minutus*, six; *Microtus agrestis*, one; *Mus musculus*, two; *Talpa europaea*, one; and *Erithacus rubecula*, one.

These records extend the host range of *Haplosporangium parvum* in Britain to three additional mammal species. The parasite is not yet known from man.

This communication was prepared at the suggestion of, and with assistance from, Dr. William L. Jellison, of the United States Public Health Service.

Attempts at Hybridization of Chickens and Turkeys which are Tolerant of Each Others' Antigens

IN a recent communication in *Nature*, Simonsen[1] described experiments which showed that injection of turkey blood into chick embryos both delayed the appearance of natural agglutinins and suppressed the formation of immune agglutinins when the young birds were injected with turkey blood some weeks after hatching. Moreover, turkeys injected as embryos with chicken blood proved to be susceptible to infection with Rous sarcoma virus at an age by which this species is normally resistant to it. Tests relating to his third purpose, namely, to see whether a sexual cross between species, which is not normally possible, could be made so by acquired tolerance, are summarized here. They do not, however, provide any evidence that the tolerant birds were more able to produce hybrid offspring than normal ones. Both Warren and Scott[2] and Quinn, Burrows and Byerly[3] obtained at least slight development in a proportion of the eggs in both reciprocal crosses between normal turkeys and chickens, although only about 1 per cent of the chicken eggs proved fertile.

In making the reciprocal crosses, semen was collected from the male birds, and the females were inseminated by the methods of Burrows and Quinn[4]. At first only semen from the blood-donor was used; later, in order to increase the volume per hen, that from several males was pooled. All eggs laid from one day after the first insemination to ten days after the last were incubated.

There were seven experimental Brown Leghorn hens which had been injected intravenously with 0·05–0·2 ml. of turkey blood on the ninth, tenth or eleventh day of incubation. Three of these had been immunized with turkey blood after hatching until their tolerance broke down. Five additional birds had been injected under the blastoderm, either before incubation or after one day in the incubator; they had received no post-hatching treatment. These twelve hens were inseminated from one to eight times each, the average being about four times, usually at intervals of three to four days. The volume of semen per insemination ranged from 0·025 to 0·1 ml. per hen, 0·1 ml. being most frequent. In all, eighty-two eggs were set: the minimum per hen was one (one hen only); the maximum, eighteen. The eggs were candled after five to seven days incubation when, without exception, they appeared 'clear'; forty-three were opened and it was confirmed that no fertilization had occurred.

Only three experimental turkeys and two controls were available. Two of the experimental birds had received intravenously 0·1 ml. of blood from a Brown Leghorn cock on the thirteenth day of incubation; the third had received the same quantity on the twentieth day. All five birds had been immunized with the cock's blood after hatching. They had been isolated from mature male turkeys throughout but, in view of the findings of Olsen and Marsden[5], several eggs from each (altogether forty-four) were incubated before insemination began, to check the possibility of parthenogenetic development; there was no evidence of this in any of them. Each bird was inseminated five or six times at intervals of three to four days; the volume given ranged from 0·2 to 0·75 ml. but was usually 0·4, 0·5 or 0·6 ml. Of six potentially fertile eggs from the controls, three developed small blood rings. Of thirty-three from the experimental birds, two developed small blood rings, nine showed slight embryonic development (less than two days), one died at about the three-day stage and one at about fifteen days. Thus approximately 50 per cent of each group showed some evidence of cellular proliferation at least. In view of the small numbers involved, the greater development in some of the eggs of the experimental birds cannot be considered significant, especially as previous workers[2,3] have obtained embryos of a still more advanced stage from normal parents.

These breeding tests therefore failed to indicate any positive effect of induced immunological tolerance on the chances of successful hybridization. It should be pointed out, however, that while the original treatment had suppressed the normal response to immunization, it had only delayed, not prevented, the formation of natural antibody; this may yet prove to be of some significance for the production of hybrids between species.

We are indebted to Mr. M. Pease for the provision of facilities at the Poultry Genetics Field Station, Boxworth, near Cambridge, for carrying out this work. One of us (M. R.) is in receipt of a personal grant from the Agricultural Research Council.

Importance of Smaller Phytoplankton Elements

MARINE biologists have been slow to recognize that the smaller phytoplankton elements which will pass through the finest nets are of great importance in the productivity of the oceans. In order to get some quantitative data on this subject for eastern Australia (lat. 33–34° S.), we have recently conducted experiments in which 44 gallons of sea-water were pumped into a drum and filtered through a phytoplankton net having 170 meshes per inch. The filtrate was collected and the particulate matter was spun out of 2-litre aliquots using a continuous centrifuge running at 13,000 rev./min. and having a slightly coned cup of maximum internal diameter 4·5 cm. and height 3·8 cm.

Both the net fraction and the centrifugate were examined microscopically, using the fluorescence of chlorophyll, to count the photosynthetic organisms, and at the same time chlorophyll determinations were made. These determinations were carried out on acetone (90 per cent) extracts of the plankton at 665μ in a Unicam *SP* 500 spectrophotometer.

It has been found that the chlorophyll content of the centrifugate is 25–3,000 times as great as that of the net plankton, while the counts of organisms are 10–10^2 as high again.

So far, no determinations have been made during diatom blooms, and it is proposed to continue these studies over an annual plankton cycle, in an estuary, and in the open sea.

From the above figures, it can be seen that the smaller phytoplankton elements (nannoplankton) may be of far greater importance than the diatoms and dinoflagellates, a fact which has been recognized by Atkins[1], Harvey[2] and others, but concerning which quantitative data are scanty.

The work discussed in this paper was carried out as part of the programme of the Division of Fisheries of the Commonwealth Scientific and Industrial Research Organization of Australia.

Further Chromosome Counts in Orobanchaceae

IN addition to the chromosome counts for British parasitic plants belonging to the Orobanchaceae already published[1], three new counts have been obtained for foreign species. *Orobanche cernua* var. *desertorum* Beck (Indian material) was found to possess a diploid complement of 38, as do other members of the subgenus *Osproleon*, while *O. ramosa* L.

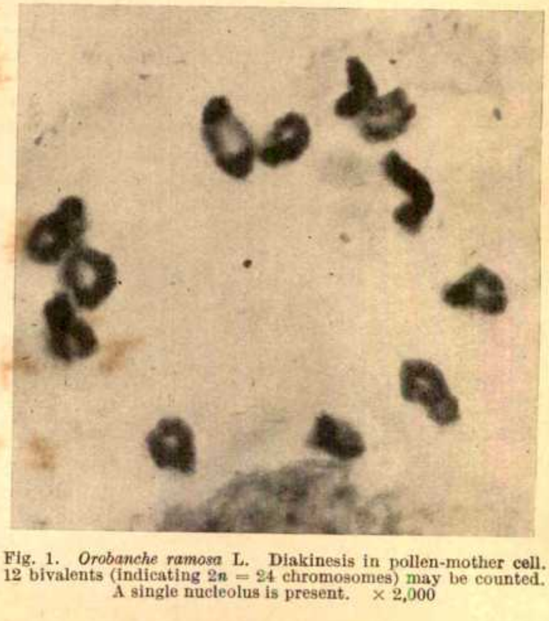

Fig. 1. *Orobanche ramosa* L. Diakinesis in pollen-mother cell. 12 bivalents (indicating $2n = 24$ chromosomes) may be counted. A single nucleolus is present. × 2,000

(German material) was found to have $2n = 24$ chromosomes, this being the number which I recorded for *O. purpurea* Jacq., another member of the subgenus *Trionychon*. *Cistanche tubulosa* Wight (Indian material) was found to have $2n = 40$ chromosomes. These three counts were made from meiotic stages in pollen-mother cells. The basic number of $x = 12$, which has been found for the two members of the subgenus *Trionychon*, may be contrasted with $x = 19$ for the members of the subgenus *Osproleon* ; it might be considered that the cytological evidence is such that the relationship between these subgenera is not so close as morphological features appear to indicate.

I am greatly indebted to Prof. Tiagi, of Government College, Ajmer, India, and to Dr. Paul Eberle, of the Botanical Institute, University of Freiburg im Bresgau, who determined, fixed and posted to me the Indian and German material respectively.

'Pearl-String' Artefacts in a Random Scatter of Spheres

FILAMENTS, similar to strings of pearl, are sometimes apparent in electron micrographs. This communication is to show that, unless other evidence is available, one is not justified in interpreting short formations of this kind as definite structures.

It has been previously shown (for example, Gross[1]) that particulate matter can be deposited in 'runs' on tilted electron microscope grids. The following experiment indicates that even in a random scattering of spheres, the discerning eye may see 'pearl strings' composed of as many as twenty-four units.

Glass spheres of about 0·1 mm. diameter (Ballotini, No. 14. English Glass Co., Ltd.) were scattered over a horizontal glass plate and projected in silhouette on to a screen. Such pearl-string formations as were readily apparent were noted and the number of spheres making up each one was recorded. The experiment was repeated a number of times with fresh scatterings of spheres. The results are given in Fig. 1. From this it is concluded that the eye readily aligns four to eight adjacent spheres into a string. There were very few scatterings in which no 'pearl strings' were seen, and they occurred particularly near the periphery of denser clusters of spheres, where presumably fairly regular packing can occur. The 'shadowing' common in electron microscopy practice could intensify the illusion of pearl strings, especially when applied to uneven, multilayer deposits.

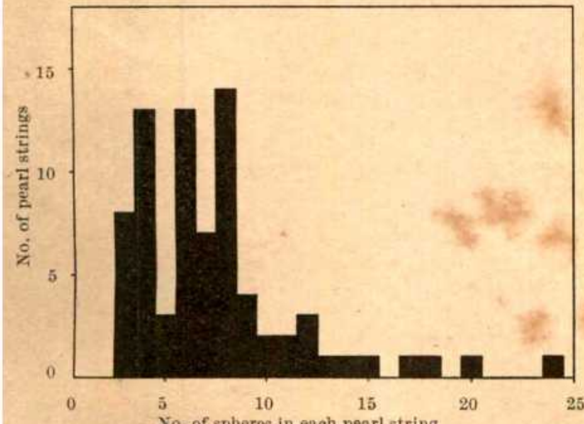

Fig. 1. Histogram showing frequency of occurrence of pearl strings of different lengths

I wish to thank Dr. A. G. Ogston for his interest, and the Medical Research Council for financial aid.

A Simple Spinning Joint for a Rotary Film Evaporator

WHEN constructing a rotary film evaporator[1] without a rotating vessel for solvent recovery, we required a spinning joint which would remain airtight at a reduced pressure of 15–20 mm. mercury.

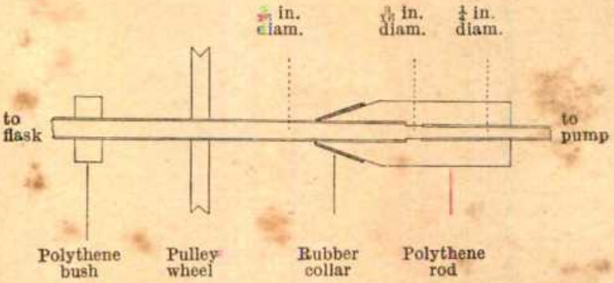

Fig. 1

A suitable joint (Fig. 1) was made using a 3-in. length of 1-in. diameter polythene rod which was drilled axially from one end to a depth of $1\frac{3}{8}$ in. with a $\frac{5}{16}$-in. bit and from the other to the same depth with a $\frac{1}{4}$-in. bit ; the bridge between the holes was drilled out using a $\frac{3}{16}$-in. bit. The rod was tapered to the larger hole and a sleeve of rubber tubing slipped over the distal part to improve the seal by constriction. A length of $\frac{1}{4}$-in. glass tubing was forced into the $\frac{1}{4}$-in. hole, the seal being improved with rubber grease ; this tube is stationary when the joint is in use. Glass tubing to fit the larger hole was carefully selected for size in order to obtain maximal ease of turning with a minimum of leaking. This was done by using a polythene washer ($\frac{5}{16}$-in. internal diameter) as a gauge. One end of the tube was carefully flamed to facilitate turning against the polythene shoulder. The flask containing the solution to be evaporated is attached to the other end. A pulley wheel to carry a belt drive was fixed part-way along this tubing. Well-constructed joints of this type when lubricated, for example, with silicone grease, will withstand the reduced pressure produced by a water pump without noticeable leaking while spinning at 120 rev./min. They have been used by us when removing hydrogen chloride and water from acid hydrolysates.

A Rapid Variable-Temperature Micro- or Macro-Dialyser

Rapidity and completeness of dialysis are favoured by a high concentration gradient at the membrane, which, in turn, depends on rapid transport of dialysable material to and from the membrane. At the same time, it is desirable in certain studies to obtain the permeate in the smallest possible volume, to simplify manipulation and to minimize the relative magnitude of analytical blank values. The apparatus is based on these considerations; it is particularly suited for dialysis of suspended materials and can be used at temperatures between 0 and 100° C. We have employed it in the study of the soluble components of bacteria (in connexion with work conducted under a research contract (*NONR*–244(00)) with the Office of Naval Research), the amount of dialysable material varying between 0·1 and 40 mgm. of total nitrogen per experiment.

The essential components are a U-tube, a polyethylene-covered magnetic stirring bar, and a horseshoe magnet which is rotated by a small motor. The assembly is shown diagrammatically in Fig. 1. Interaction between the rotating outside magnet (arranged by trial) and the inside magnet moving up-and-down causes rhythmic movements of the casing and agitation of its contents. For larger assemblies the stroke of the inside magnet may be lengthened by putting two magnets end to end (UU) into the clamp. Continuous renewal of the outside fluid is provided by running water slowly through the U-tube. Temperature control is maintained by placing the assembly in a suitable bath. For temperature equilibration the water enters at the bead-filled leg of the tube. The permeate may be sampled or collected in aliquots at the other end. Connexions are made with polyethylene tubing which can be used up to 105°. 'Tygon' tubing releases ultra-violet-absorbing substances.

In order to avoid contaminations when dealing with low levels of nitrogen, rubber gloves should be used for knotting the cellulose casing, and water purified with 'Amberlite *IR*–120' for dialysis. 'Nojax' casings show no evidence of mechanical weakening after several hours in boiling water.

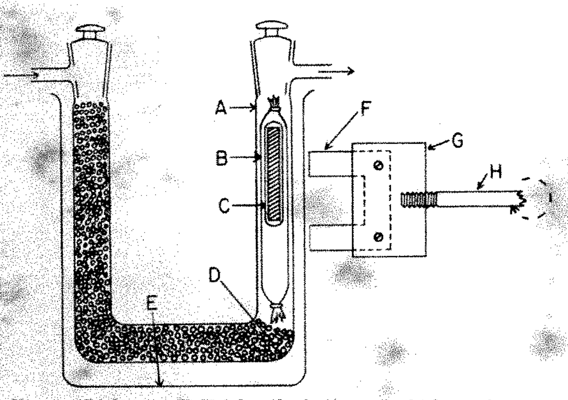

Fig. 1. Dialyser. *A*, U-tube, the bottom of which can be constricted to prevent beads from shifting into the right arm (absorption tubes, Schwartz, *T* 12/30 to 24/40 (the legs may be lengthened), No. *J*-310, Scientific Glass, Bloomfield, N.J.). *B*, dialysis casing knotted on both ends. *C*, stirring bar consisting of 2–6 cm. pieces of rod magnet slipped into polyethylene tubing, the ends being sealed by gentle heat (rod magnets, ⅛–⅜ in., Alnico grade 2 or 3, magnetized lengthwise, Permag Corp., Brooklyn 5, N.Y., covered with 'Intramedic' polyethylene tubing, wall thickness between 0·3 and 0·6 mm., No. *PE* 350 to *PE* 440. Clay-Adams, New York 10, N.Y.). *D*, 4 mm. glass beads. *E*, beaker. *F*, horseshoe magnet (rectangular U-magnet, outside length 1¾ in., inside length ¾ in., No. 71 *D* 778 *P* 4, Permag Corp.) held by aluminium clamp (*G*) and (*H*) the motor shaft (24 rev. per min. electric motor, No. 4 *K* 237, W. W. Grainger Co., Philadelphia, Pa.). The shaft should turn at about 10 rev. per min. The external water space of the U-tube ranged from 15 ml. for a 3-ml. dialysis casing ('Nojax' casing, 8/32 or 18/32 in. diameter, Visking Corp., Chicago 38, Ill.) to 100 ml. for a 50-ml. casing

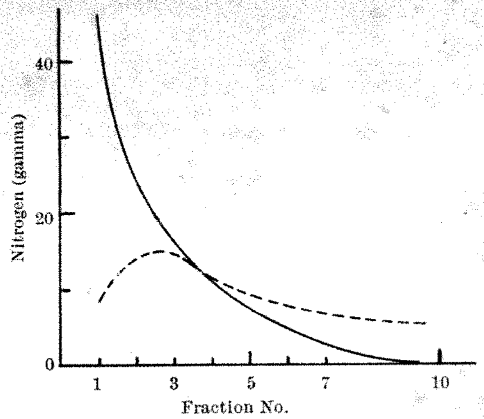

Fig. 2. Effect of agitation. Equal suspensions (43 mgm. dry) of washed lyophilized bacteria were dialysed (3 ml. inside volume) against water (1 ml. per min.) without (dash line) and with (full line) magnetic agitation at room temperature. The nitrogen content of successive 25-ml. fractions of the permeate is shown

Acceleration of dialysis by agitation has been demonstrated[1]. Fig. 2 shows the effect of inside agitation under our experimental conditions. At the time dialysis is complete with inside agitation, the yield is 50 per cent without agitation. Another example may illustrate the practical efficiency of the proposed method: 400 mgm. of dry bacterial substance suspended in 5 ml. water yielded, in 100 min. of dialysis, during the first 40 min. of which the bath was kept at 100°, a permeate of 100 ml. which contained 2·24 mgm. ninhydrin-nitrogen. Further exhaustive dialysis (250 ml.) yielded an additional 0·07 mgm.

Quotation of Titles of Papers in Review Articles

I wish to support Dr. Charity Waymouth's plea for the inclusion of titles of papers in the bibliography of a review article.

The editors of "Advances in Virus Research" asked me for a review. I looked at volume 1, the only one then published, and found a very pleasing chaos in the manner of citing references and some authors gave titles in full. I had half written my review when I realized that dull conformity had descended on the journal and that, worse still, it took the form of eliminating titles. To withdraw the article would have meant wasting the time already spent on it so I simply protested, and I welcome the opportunity of protesting again.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, March 5

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 4.30 p m.—Annual General Meeting. 5.30 p.m.—Prof. L. Rosenfeld: "Success and Failure in the Growth of Science".

University College, London (in the Physiology Theatre, Gower Street, London, W.C 1), at 5 p.m.—Prof. S. Spiegelman (U.S.A.): "The Present Status of the Enzyme-Forming Mechanism".*

Society of Engineers (at the Geological Society of London. Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. A. A. Fulton: "The Present Trends in Hydro-Electric Development".

University of London (at Birkbeck College, Malet Street, London, W.C.1), at 5.30 p.m.—Dr. Anton Bruun (Copenhagen): "The Abyssal Fauna—its Ecology, Distribution and Origin".* (Further Lectures on March 7 and 9.)

University of London (at King's College, Strand, London, W.C.2), at 5.50 p.m.—Dr. J. M. Zarek: "Biomechanics of the Human Femur" *

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"South". (The original film of Shackleton's Imperial Trans-Arctic Expedition.)

Society of Chemical Industry, London Section (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 15 p.m.—Meeting on "The Production and Uses of Sequestering Agents".

Tuesday, March 6

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. P. R. Bell: "'Kon Tiki' and the Botanists".*

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5.30 p.m.—Mr. F. Roberts and Mr. B. T. Bell: "Horizontal Mixer-Settler Equipment".

University of London (at Birkbeck College, Malet Street, London, W.C.1), at 5.30 p.m —Prof. K. Kuratowski (Warsaw): "Some Topological Problems Concerning Complete Metric Spaces".* (Further Lectures on March 9 and 13.)

University of London (at King's College, Strand, London, W.C.2), at 5 30 p.m.—Prof. D. W. G Style: "Some Problems in Chemistry" (Inaugural Lecture).*

Tuesday, March 6—Friday, March 9

Ciba Foundation (at 41 Portland Place, London, W.1)—Symposium on "Influence of Ionizing Radiations on Cell Metabolism".

Wednesday, March 7

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir Charles Dodds, F.R.S.: "The Debt of Chemistry to Medicine" (Pope Memorial Lecture).

Royal Aeronautical Society (in the Hall of La Société des Anciens Élèves des Écoles d'Arts et Métiers, 9 bis avenue d'Iena, Paris 16), at 5 p.m.—Mr. E. T. Jones: "A Philosophy of Aeronautical Research" (Ninth Louis Bleriot Lecture).

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. I. S. Groundwater: "The Maintenance of High Efficiencies on Economic Boilers—a Record of Operating Experience".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. D. N. Keep: "Frequency-Modulation Radar for Use in the Mercantile Marine".

Royal Institute of Chemistry, London Section (joint meeting with the Chelsea Polytechnic Chemical Society, at the Chelsea Polytechnic, Manresa Road, London, S.W.3), at 7 p m.—Mr. R. C. Chirnside: "Analytical Chemistry, Chemical Analysis and the Analyst".

Thursday, March 8

Royal Society (at Burlington House, Piccadilly, London, W.1), at 11 a.m.—Discussion on "Immunological Tolerance". Opening Speakers: Sir Macfarlane Burnet, F.R.S., and Prof. P. B. Medawar, F.R.S.

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. B. B. Boycott: "Brains".*

Society of Cosmetic Chemists of Great Britain (at the Royal Society of Arts, John Adam Street, London, W.C.2), at 7.30 p.m.—Mr. A. de Waele: "Technically Useful Rheology".

Friday, March 9

Operational Research Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Dr. B. V. Bowden, Mr. D. Owen and Dr. S. H. Hollingdale: "The Influence of Data Processing Machines on Operations".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Influence of Size and Shape on the Testing of Materials".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. P. I. Dee, F.R.S.: "Radioactive Isotopes and Their Applications".

Saturday, March 10

Chester Beatty Research Institute, Photobiology Group (in the Chemistry Lecture Theatre, Chelsea Polytechnic, Manresa Road, London, S.W.3), at 10 a.m. and 2.15 p.m.—Scientific Papers.

Nutrition Society (at the London Hospital Medical College, Turner Street, London, E.1), at 10 30 a.m.—Symposium on "Diet and Anœmia". Chairman: Prof. Sir Stanley Davidson.

London County Council (at the Horniman Museum, London Road, Forest Hill, London. S E.23) at 3.30 p.m.—Prof. J. R. Firth: "The Uses and Abuses of Translation".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with teaching, research and/or industrial experience) in Physics—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (March 9).

Reactor Technologists (Engineers or Chemical Engineers) at Dounreay Works, Caithness, Scotland, for work which involves providing engineering assistance to the Reactor Managers to whom they will be directly responsible—The Recruitment Officer, Industrial Group Headquarters, United Kingdom Atomic Energy Authority, Risley, near Warrington (March 9).

Lecturer (with a good honours degree and teaching experience, and preferably with industrial or research experience) in Physical or Organic Chemistry—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (March 10).

Physicist or Electrical Engineer (with a first- or second-class honours degree in physics or electrical engineering, or equivalent qualifications, and experience in the development of electronic equipment) at the Ministry of Supply London Headquarters, for co-ordination of development of airborne radar equipment including liaison with Research and Development Establishments, the Services, and industry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.49/6A/BN (March 10).

Senior Grade Biochemist (qualified in science (B Sc. or A.R I.C.), and at least five years experience of hospital biochemistry), at the Western Infirmary, Glasgow—The Secretary and Treasurer, Board of Management for Glasgow Western Hospitals, 10 Park Circus, Glasgow, C.3 (March 10).

Senior Lecturer (with an honours degree and teaching experience, and also research or industrial experience) in Physics, and Research Assistants (2) (with a good honours degree, or equivalent, in physics) in Physics or Electronics—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (March 10).

Assistant Lecturer or Lecturer in Mathematical Statistics in the Department of Applied Mathematics—The Registrar, The University, Liverpool (March 12).

Principal Scientific Officer (with an appropriate university degree of high standard together with extensive relevant research experience, proven capacity to initiate and conduct research, and with experience in staff control) at the Weapons Research Establishment, Department of Supply, Salisbury, South Australia, to direct a group responsible for basic studies of guided weapons systems using mathematical techniques and analogue computers, and to be responsible for the development of computers and associated techniques—The Senior Representative (AP.44), Department of Supply, Australia House, Strand, London, W.C.2 (March 15).

Senior Scientific Officer (at least 26, with a first- or second-class honours degree in mathematics, physics or engineering, or equivalent, at least three years postgraduate research experience and a keen interest in new developments) in the Research Section of the Performance Division, Aeroplane and Armament Experimental Establishment, near Amesbury, Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.43/6A (March 15).

Lecturer in Educational and Applied Psychology—The Secretary of University Court, The University, Glasgow (March 17).

Chair of Geology—The Registrar, University College, Singleton Park, Swansea (March 20)

Assistant Lecturer in the Department of Zoology—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (March 23).

Lecturer in Biological Chemistry—The Secretary, The University, Aberdeen (March 24).

Senior Geomorphologist (with a university honours degree with considerable experience in field geomorphology, and proved research and organizational ability) in the Land Research and Regional Survey Section, Commonwealth Scientific and Industrial Research Organization, Canberra, to direct and further develop geomorphological studies in a research section concerned with the description, mapping and potential assessment of under-developed regions of Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C 2, quoting 570/39 (March 24).

Edward A. Deeds Senior Fellow at Queen's College, Dundee, for research in Engineering, Metallurgy, Chemistry, Physics, Mathematical Physics or any cognate subject—Joint Clerk to the University Court, The University, St. Andrews (March 31).

Probationary Assistant Lecturer, and a Lecturer, in the Department of Zoology—The Registrar, University College, Singleton Park, Swansea (March 31).

SENIOR LECTURER (with a higher degree in psychology) IN PSYCHOLOGY at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, March 31)

SENIOR RESEARCH OFFICER IN THE LABORATORY OF HUMAN NUTRITION—The Whitley Professor of Biochemistry, Department of Biochemistry, The University, Oxford (April 1).

ASSISTANT LECTURER IN MATHEMATICS—The Registrar, University College, Leicester (April 7).

BROWNE RESEARCH FELLOW (graduate of a university in the British Isles) IN BOTANY OR ZOOLOGY—The Provost, The Queen's College, Oxford (April 14).

LECTURER (preferably with a sound general training in geology and with experience in one or more of the following: civil engineering, geology, mining geology or geology of coal) IN ECONOMIC GEOLOGY—The Registrar, King's College, Newcastle-upon-Tyne (April 14).

BERKELEY BYE-FELLOW (not less than 26 years of age) for research in medicine—The Registrary, Gonville and Caius College, Cambridge (April 30).

CHAIR OF CULTURAL ANTHROPOLOGY at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Johannesburg, April 30).

ASSISTANT EXPERIMENTAL OFFICER (graduate, with mathematics and agricultural interests) IN THE STATISTICAL UNIT—The Secretary, Grassland Research Institute, Hurley, Maidenhead.

ASSISTANT (Grade B) to teach pure and applied mathematics to higher national certificate and degree level—The Principal, Huddersfield Technical College, Queen Street South, Huddersfield.

BIOCHEMIST, Scientific Officer or Senior Scientific Officer grade (preferably with not less than two years postgraduate research experience either in carbohydrate or protein biochemistry) to work in the PHYSIOLOGY DEPARTMENT on mammary gland metabolism—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting 56/1.

CHEMIST, Superintendent Level (with a first- or second-class honours degree, with experience in the control and operation of analytical laboratories, preparative chemistry (mainly organic) and the scaling up of processes to pilot plant scale, and knowledge and experience of the control of hazardous operations and ability to organize industrial labour)—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 1027/34.

GRADUATE (metallurgy, chemistry or physics) IN THE INFORMATION DEPARTMENT for work dealing with every aspect of recording and transmission of information on the extraction, manufacture and uses of non-ferrous metals and their alloys—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

LECTURER or ASSISTANT LECTURER (with a good honours degree in metallurgy and preferably also works or research experience) IN METALLURGY—The Registrar, The University, Nottingham.

MASTER TO TEACH PHYSICS and some General Science—The Headmaster, Alleyn's School, Dulwich, London, S.E.22.

METALLURGIST (with B.Sc. (metallurgy), A.I M , or equivalent, and experience in metallographic work and mechanical testing, and preferably some experience of welding problems) AT THE CENTRAL LABORATORY, CHISWICK—Recruitment and Training Officer (F/EV.568), London Transport, 55 Broadway, London, S.W.1.

PROFESSORS OF STRUCTURAL ENGINEERING, HYDRAULIC ENGINEERING, SOIL ENGINEERING, MECHANICAL ENGINEERING, MECHANICAL ENGINEERING (with special qualifications in machine design and thermodynamics), INDUSTRIAL MANAGEMENT AND PRODUCTION ENGINEERING, ELECTRONICS, CHEMICAL ENGINEERING, AERONAUTICAL ENGINEERING, MATHEMATICS, PHYSICAL CHEMISTRY, GENERAL AND INORGANIC CHEMISTRY, at the Israel Institute of Technology, Haifa, Israel—The Secretary, The Technion Society of Great Britain, 83 Wimpole Street, London, W.1.

RESEARCH ASSISTANT (graduate, man or woman, with a special interest in plant physiology) IN BOTANY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

RESEARCH ASSISTANT IN THE FLUID DYNAMICS SECTION OF THE PHYSICS DEPARTMENT, to join a team studying dust and fume in gas streams and allied subjects—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "F.D.3".

RESEARCH FELLOW (with a zoology or veterinary degree, and preferably with postgraduate experience in protozoa) IN PROTOZOOLOGY, for duties which will include investigations of protozoan parasites of wild and domestic animals of Queensland—The Registrar, University of Queensland, Brisbane, Australia.

SENIOR PHYSICAL CHEMIST (with postgraduate degrees and extensive experience in applied research and preferably with experience in high polymers, permeability of materials, flame-proofing, rubber, textiles, and plastics, or other aspects related to the development of protective coverings) WITH THE DEFENCE RESEARCH BOARD, Ottawa, Canada—Defence Research Member, Canadian Joint Staff, Moncorvo House, 66 Ennismore Gardens, London, S.W 7.

TECHNICIAN or SENIOR TECHNICIAN (male or female, preferably with a degree in geography, cartographic skill, and some experience of photographic work) IN THE GEOGRAPHY DEPARTMENT—The Professor of Geography, University College of North Staffordshire, Keele, Staffs.

PERMUTIT ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

LECTURES AND COURSES

BIRKBECK COLLEGE

(UNIVERSITY OF LONDON)
SESSION 1956-1957 BEGINS MONDAY
OCTOBER 1, 1956

Part-time (Evening) Courses provided for Internal Degrees in the Faculties of Arts and Science and for the Academic Postgraduate Diploma in Psychology. Facilities also provided for part-time and full-time students reading for higher degrees in arts and science. Applications for admission should be made before June 1.

Pamphlet and form of application may be obtained from the Registrar, Birkbeck College, Malet Street, W.C.1.

UNIVERSITY OF LONDON

A course of two lectures on "The Future of Pharmacy in relation to World Needs" will be given by Brigadier-General Sir Harold Hartley at 5.30 p.m., on March 7 and 15 at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1.

Admission free, without ticket.

JAMES HENDERSON,
Academic Registrar

UNIVERSITY COLLEGE

LONDON (GOWER STREET, W.C.1)

Professor S. Spiegelman (University of Illinois) will give a Public Lecture entitled "The Present Status of the Enzyme-forming Mechanism" on Monday, March 5 at 5 p.m.

Admission free, without ticket.

E. A. L. GUETERBOCK,
Secretary.

OFFICIAL APPOINTMENTS

The engagement of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 *to* 64 *inclusive, or a woman aged* 18 *to* 59 *inclusive, unless he or she, or the employment, is excepted from the provisions of the Notification of Vacancies Order,* 1952.

CHELSEA POLYTECHNIC

MANRESA ROAD, S.W.3
DEPARTMENT OF PHYSICS
Head of Department: Dr. W. H. George,
M.Sc., Ph.D.(Lond.), F.Inst.P.

Applications are invited for the post of full-time Lecturer in Physics. Candidates should possess teaching, research and/or industrial experience. Research or industrial experience with electronic circuits would be an advantage. Ample time and facilities for research will be provided. The salary scale is as follows: men, £965 by £25 to £1,065 per annum; women, £799 11s. by £20 to £1,065 per annum, plus London allowance of £36 or £48 according to age. Placing on the scale will be in accordance with previous service in a similar capacity.

Further particulars and form of application may be obtained by sending stamped addressed foolscap envelope to the Clerk to the Governors. Applications must be returned not later than March 9, 1956.

UNIVERSITY OF WESTERN ONTARIO

DEPARTMENT OF PHYSICS
RESEARCH ASSOCIATESHIPS IN EXPERIMENTAL AND THEORETICAL PHYSICS

Applications are invited for postdoctoral and predoctoral research associateships in experimental and theoretical physics tenable in The Molecular Excitation Group from August, 1956.

The research interests of the group cover a wide range of excitation problems related to Astrophysics, Atmospheric Physics and Combustion.

Further information may be obtained by writing by airmail to Dr. R. W. Nicholls, Department of Physics, University of Western Ontario, London, Ontario, Canada.

UNIVERSITY COLLEGE OF NORTH STAFFORDSHIRE

Applications are invited for the post of Demonstrator in Geography for the summer term 1956 and the session 1956-57. Special interest in cartography desirable. Salary £450 per annum.

Application forms, to be returned not later than March 12, from the Registrar, The College, Keele, Staffs.

MANCHESTER COLLEGE OF TECHNOLOGY

APPOINTMENT OF FULL-TIME TEACHER IN THE DEPARTMENT OF APPLIED PHYSICS

The Governing Body invites applications for the appointment of a full-time Teacher in the workshop in the Department of Applied Physics. The work involves both teaching and instrument construction. The teaching duties involve instruction in the elements of workshop practice to students of applied optics in the college and to university science students. Experience of the specialized techniques of ophthalmic optics is particularly desirable. The assistant, who will be responsible to the professor of applied physics, will be in charge of a teaching workshop, and will have access to the departmental workshop which is fitted with a good range of machine tools. Salary scale: £525 per annum, rising by annual increments of £25 and one final increment of £20 to a maximum of £820. Subject to this maximum not being exceeded, one increment of £18 will be added to the minimum in respect of each year of approved industrial experience up to a maximum of twelve, together with one further increment (usually of £18) for each year of previous full-time teaching service. There are also certain additional training and graduate allowances.

Form of application may be obtained from The Registrar, College of Technology, Manchester, 1. Last date for the receipt of applications is Saturday, March 17, 1956.

B. V. BOWDEN,
Principal

UNIVERSITY OF GLASGOW

Applications are invited for the post of Demonstrator in Chemistry (inorganic, organic and physical). The remuneration will be £350 per annum and appointments will be made initially for one year from October 1, 1956, renewable for up to three additional years. The duties of the Demonstrators appointed will be to assist in the teaching of practical chemistry. Ample time will be allowed for the prosecution of research and Demonstrators will be expected to register for the degree of Ph.D. in this University.

For forms of application apply to the Secretary of the University Court, The University, Glasgow, W.2.

MATHEMATICIANS OR STATISTICIANS required by Ministry of Supply, Ordnance Board, London, for experimental design and analysis of trials mainly connected with A.A. weapons and fire control systems. Knowledge of calculating machines may be an advantage. Candidates should possess first- or second-class honours degree or equivalent. Salaries according to age, experience, etc., within range, Scientific Officer (minimum age 21) £513 10s. to £925; Senior Scientific Officer (minimum age 26) £1,070 to £1,245; Principal Scientific Officer (minimum age 31) £1,245 to £1,670 (superannuable). Candidates for senior posts must have some years suitable postgraduate research experience.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A70/6A/BN.

THE NATURE CONSERVANCY REQUIRE an Assistant (male) for recording vegetation changes resulting from death of rabbits through the spread of myxomatosis, to be based on London but considerable travelling involved. Minimum qualifications general certificate of education ordinary level in 4 subjects, including English language and biology; general certificate of education to advanced level botany an advantage. Starting salary between £240 and £423 according to age. The post is non-pensionable with pension prospects.—Applications, giving details of age, educational qualifications, with particulars of examinations and subjects, National Service, previous posts, relevant interests, and names and addresses of two referees, one qualified to speak for ability in the duties and one for character and health, to Establishment Officer, the Nature Conservancy, 19 Belgrave Square, London, S.W.1, before March 10, 1956.

MINISTRY OF AGRICULTURE, FISHERIES and Food requires temporary Assistant Technical Officer at Kendal. Duties concerned with (i) production and distribution of agricultural lime, (ii) fertilizer subsidy. Travelling involved. Qualifications: degree in agriculture, aged at least 21. Starting pay (men) £543 10s. if 25 or over; less below age 25. Maximum (provincial) £830; lower for women. Extra duty allowance 3 per cent.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G 238/5A.

MINISTRY OF SUPPLY

SENIOR PRINCIPAL SCIENTIFIC OFFICER

The Civil Service Commissioners invite applications from men for the pensionable appointmen of Safety Officer at the Microbiological Researc Department, Porton, Wilts. Candidates must be at least 32 on December 31, 1956. They mus have a medical qualification and a proven knowledge of, and interest, in, microbiology. They will be responsible for research in the field of ai hygiene. Experience of methods of air sampling and of air sterilization desirable. They will also be required to undertake medical duties, such as routine immunization of staff. Salary scale £1,700 to £1,950. Starting salary above minimum may be granted according to qualifications and experience.

Further particulars and application forms from Civil Service Commission, Scientific Branch, 3 Old Burlington Street, London, W.1, quoting No S 4564/56/9. Application form must be returned by March 17, 1956.

UNIVERSITY OF LEEDS

DEPARTMENT OF CIVIL ENGINEERING

Applications are invited for appointment as Lecturer in Civil Engineering at a salary on the scale £650 by £50 to £1,350 a year, according to qualifications and experience. Candidates should have an honours degree and practical experience in Public Works Engineering.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of three referees, should reach the Registrar, The University, Leeds, 2 (from whom further particulars may be obtained), not later than March 31, 1956.

QUEEN MARY COLLEGE

(UNIVERSITY OF LONDON)
MILE END ROAD, E.1.

Applications are invited for the post of Assistant Lecturer in the Department of Zoology. Salary scale £600 by £50 to £700 with F.S.S.U. participation and family allowance of £50 for each child.

Application forms, obtainable from the Registrar, to be returned by March 23.

SENIOR SCIENTIFIC OFFICER OR SCIENtific Officer required by Ministry of Supply at Aeroplane and Armament Experimental Establishment, near Amesbury, Wilts., for development of test methods, techniques and specialized instruments for use in trials of aircraft armament systems. Candidates should have a first- or second-class honours degree or equivalent in physics, electrical engineering or maths. Sound knowledge of electronics, light electro-mechanical equipment or armament assessment problems desirable. At least 3 years' postgraduate research experience required for Senior Scientific Officer. Salary within range: Senior Scientific Officer £1,030 to £1,185; Scientific Officer £488 10s. to £885 (superannuable). Houses become available from time to time for successful married candidates.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London S.W.1, quoting A 63/6A/BN.

INFORMATION OFFICERS REQUIRED IN London in the Public Relations Branch of the United Kingdom Atomic Energy Authority. Applicants (preferably between 24 and 30 years of age) should either be scientists or engineers, or people already experienced in public relations, journalism, lecturing or exhibition work, who have some technical background. They should be able to write and/or speak well and interpret technical information to the general public. Successful applicants will work to public relations specialists and will be able to extend their knowledge of publicity techniques. Starting salary, depending on age, experience, and qualifications, within the scale £975 to £1,188. Contributory pension scheme.—Send postcard for application form to Room 22, U.K.A.E.A., 14 Ormond Yard, St. James's, London, S.W.1.

AERODYNAMICISTS AND MATHEMATIcians required by Ministry of Supply for various Experimental Establishments and London H.Q., for research and development work on aircraft projects, performance analysis of aircraft and weapons, statistics and operational research, guided weapons, gas turbines. Candidates should have a first- or second-class honours degree or equivalent. Some research or development experience would be useful. Appointments initially as Scientific Officer (minimum age 21) within salary range, £488 10s. to £885 (Provinces), £513 10s. to £925 (London) (superannuable).—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 69/6A/BN.

OCONUT RESEARCH INSTITUTE
(CEYLON)
POST OF DIRECTOR

The Coconut Research Board of Ceylon invites pplications for appointment as Director of the oconut Research Institute of Ceylon 1. Salary: ocal candidates, Rs 18,000 by Rs.800 to s.30,000 per annum; Overseas candidates, 2,000 by £100 to £3,500 per annum at current xchange rates. A dearness allowance of 15 per ent of basic salary, a rent-free two-storey house ith heavy furniture is provided. A successful pplicant will be required to contribute to a rovident fund at the rate of 15 per cent of his asic salary and an equivalent amount will be aid by the Board A higher salary would be corded *ad personam* to a successful applicant ith eminent qualifications. The appointment ill be in the first instance for a period of four ears, inclusive of six months end of contract ave. It is terminable with three months' notice n either side. A first-class sea passage to eylon will be provided for an overseas candidate, is wife and children under the age of 18 years imilarly, return passages will be provided to the ountry of domicile at the end of the period of ervice. Leave and travelling allowances in eylon will be in accordance with the regulations f the Institute 2. Qualifications: The post calls or proved high scientific attainments, preferably fields related to soils or crops combined with dministrative experience either as head or deputy the organization and running of a research stitute or university department. Experience of opical conditions would be an advantage, but is ot an essential qualification. 3 Functions: The irector's primary responsibilities to the Coconut esearch Board will be the administration of the nstitute and the direction of the research actities of the Institute for the improvement of the eld and quality of the products of the palm. He ill also be responsible to the board for the administration of replanting, rehabilitation and new lanting schemes for the Island and for public elations. General: The laboratories of the Institute are situated in the main coconut growing area f the Island, 32 miles north of Colombo. There a scientific staff engaged in technological chemisy, soil chemistry, agronomy, plant breeding, and op protection. 4. Applications: Particulars hould be furnished by applicants of their age, arital status, academic qualifications, and research and administrative experience. They hould also provide a list of publications, copies f testimonials, and the names and addresses of e referees to whom confidential inquiries can e addressed. A medical certificate and a recent hotograph should also be annexed to the application.

Further particulars, if required, may be obtained rom the undersigned. Applications should reach he Chairman, Coconut Research Board, Departent of Agriculture, Peradeniya, Ceylon, on or efore March 31, 1956.

Chairman.
Coconut Research Board of Ceylon.

BOURNEMOUTH EDUCATION COMMITTEE
BOURNEMOUTH MUNICIPAL COLLEGE OF TECHNOLOGY AND COMMERCE

Required, as soon as possible, Head of Science epartment, Physics, Chemistry, Biology and Mathematics. Applicants should have a good deee in physics or chemistry Technical College aching and industrial experience are desirable. Salary in accordance with Burnham Technical cales, 1954, for Grade II Head of Department Application forms and further particulars obinable from W. R Smedley, Chief Education Officer, Town Hall, Bournemouth, returnable by March 17.

UNIVERSITY OF ST. ANDREWS
QUEEN'S COLLEGE, DUNDEE
LECTURESHIP IN ENGINEERING

Applications are invited for appointment as ecturer in Mechanical Engineering in the Department of Civil and Mechanical Engineering, Queen's College, Dundee, to commence October 1, 1956. The candidate appointed would be quired to assist with the teaching and to take part in the research work of the department Opportunities will be granted to work for a higher egree. Salary scale £650 by £50 per annum to 1,350, with efficiency bar at £1,000 and commencing salary according to experience and qualifications. F.S S.U and family allowance benefits; a grant towards expenses of removal may be made. Six copies of the application, hich should contain the names of three referees, o the undernoted not later than April 18, 1956

PATRICK CUMMING,
Joint Clerk to the University Court.
Queen's College, Dundee.

SENIOR PHYSICAL CHEMIST

Initial Salary $6,000 to $8,000 per annum
DEFENCE RESEARCH BOARD
CANADA

A Senior Physical Chemist with post-graduate degrees and extensive experience in applied research is required for location in Ottawa. Experience in high polymers, permeability of materials, flame-proofing, rubber, textiles, and plastics, or other aspects related to the development of protective coverings would be an advantage. Extensive experience in the direction of applied research with a view to the development of end items is essential.

Generous holiday, sick leave, pension and insurance benefits included.

Apply to:

Defence Research Member,
Canadian Joint Staff,
Moncorvo House,
66 Ennismore Gardens,
London, S.W.7, England.

UNIVERSITY OF MANCHESTER
I.C.I. FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Imperial Chemical Industries Ltd., tenable in the University and available for research in chemistry, physics and allied subjects, e.g., pharmacology, engineering, metallurgy. The value of the Fellowships will be within the range of £600 to £900 per annum according to qualifications and experience.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester, 13, to whom applications should be sent not later than April 30, 1956

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for (i) a Probationary Assistant Lectureship and (ii) a Lectureship in the Department of Zoology. Salaries: Assistant Lectureship, not less than £550 per annum, Lectureship £650 by £50 to £1,350 per annum Commencing salary in each case will be at a point on the appropriate scales according to qualifications and experience. The initial salary for the Lectureship will not be higher than £1,000. Membership of the F.S S.U. and children's allowance scheme

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications (five copies) must be sent by Saturday, March 31, 1956.

THE ROYAL SOCIETY
TROPICAL RESEARCH FELLOWSHIP
(MEDICAL SCIENCES)

Applications are invited by the Council of the Royal Society for a Research Fellowship with special reference to ill health in the tropics. The Fellowship is tenable in any university, hospital or medical school or other institution approved by the Royal Society in the British Commonwealth The successful applicant, who need not necessarily hold a medical qualification will be expected to spend some part of the period of tenure in the tropics The appointment will be for two years in the first instance, from October 1, 1956, and may be renewed annually up to a total of five years It will be subject to the conditions governing Royal Society Research Appointments. The stipend will be £1,250 per annum.

Applications, which should be made on forms to be obtained from the Assistant Secretary, The Royal Society, Burlington House, London, W 1, should be received as early as possible, in any case not later than April 6, 1956.

WHITCHURCH AND ELY HOSPITAL MANAGEMENT COMMITTEE
CARDIFF RADIOTHERAPY CENTRE

This unit is situated at Whitchurch in the vicinity of Cardiff. It is an entirely new building and comprises an extensive treatment centre and ward accommodation for some 72 patients. The therapeutic equipment will include both superficial and deep X-ray plant together with rotating cobalt units. There is also a large mould room and a radio-isotopes suite.

Applications are invited for the following appointments in the Physics Department: 1 Physicist (Basic Grade): candidates should possess a first- or second-class honours degree in physics. Salary scale for a probationary period of at least two years £525 by £25 to £625. (After satisfactory probationary period appropriate scale £650 to £845.) Postgraduate study or experience may be considered in fixing the starting salary. 1 Physicist (Senior Grade): candidates should possess a first- or second-class honours degree in physics and previous experience in hospital physics Salary £910 by £40 to £1,230. The successful candidates may be required to attend at other hospitals in the region, including the United Cardiff Teaching Hospitals.

Applications, stating age, qualifications and previous experience together with the names of two referees, should be forwarded to the Group Secretary, Whitchurch and Ely Hospital Management Committee, Group Office, Whitchurch Hospital, Cardiff.

GONVILLE AND CAIUS COLLEGE, CAMBRIDGE
BERKELEY BYE-FELLOWSHIP

Founded in memory of Sir G. H. A. Comyns Berkeley and of his wife, Ethel Rose Berkeley The Council of Gonville and Caius College invite applications for a Berkeley Bye-Fellowship for research in Medicine. Candidates should be men of not less than 26 years of age. The tenure of the Bye-Fellowship is for one to three years and the emolument from £700 to £1,250 a year according to standing. Full particulars may be obtained from the Registrary, Gonville and Caius College, Cambridge.

Applications must be received not later than April 30, 1956.

UNIVERSITY COLLEGE OF NORTH STAFFORDSHIRE

Applications are invited from suitably qualified persons (male or female) for the post of Technician or Senior Technician in Geography Department. Degree in geography desirable but not essential; cartographic skill required, some experience of photographic work an asset. The successful candidate will be required to act also as meteorological observer, and the necessary training will be given Salary scales £340 to £480 (Technician), £490 to £590 (Senior Technician). Residential accommodation for a single person may be available

Application forms from Professor of Geography, The College, Keele, Staffs.

UNIVERSITY OF MANCHESTER
TURNER AND NEWALL RESEARCH FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Messrs. Turner and Newall Ltd., tenable in the University and available for research in engineering, inorganic chemistry, physics and allied subjects. The value of the Fellowships will be within the range of £600 to £900 per annum according to qualifications and experience.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester, 13, to whom applications should be sent not later than April 30, 1956.

RAMSAY MEMORIAL FELLOWSHIPS FOR ADVANCED STUDENTS OF CHEMISTRY

The Trustees will consider in June, 1956, applications for two Fellowships, normally tenable for two years One will be limited to candidates educated in Glasgow, who can apply to be considered for either Fellowship. Value of each Fellowship £600 per annum, plus expenses grant up to £100 per annum.

Full particulars from Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, London, Gower Street, W.C.1 Completed application forms must be received by April 20, 1956.

CIVIL ENGINEERS FOR DEPARTMENT OF MAIN ROADS

NEW SOUTH WALES, AUSTRALIA

Applications are invited from graduates (or undergraduates in their final year) in civil engineering of a recognized British or Irish university for appointment to the staff of Department of Main Roads, New South Wales, the State Road Authority for construction of roads and bridges.

On appointment applicants may be engaged at the Department's Head Office, Sydney, on the design of reinforced concrete and steel bridges or on main road construction and maintenance either in the metropolitan area or the country Commencing salary according to qualifications and experience will be within the range £A 1,046 to £A.1,299 per annum, with annual progression subject to technical competence, to £A.1,585 per annum. Appointees will be eligible to contribute to the State Superannuation Fund after six months. Appointee's full fare from England to Australia will be met by the Department, subject to a three years' service guarantee bond being completed. Appointment will be subject to satisfactory medical examination and preference will be given to applicants not more than 30 years of age.

Applications should be made on forms obtainable from the Agent General for New South Wales, 56 Strand, London, W.C 2.

UNIVERSITY OF LIVERPOOL

Applications are invited from candidates with experience in either experimental or theoretical physics for posts of Lecturer in the Department of Physics, where there are good facilities for research work in nuclear physics The initial salaries will be within the range £650 to £1,350 per annum, according to qualifications and experience and the duties of the posts will commence on October 1, 1956.

Applications, stating age, academic qualifications and experience, together with a list of publications and the names of two referees, should be received not later than March 29, 1956, by the undersigned, from whom further particulars of the conditions of appointment may be obtained.

STANLEY DUMBELL,
Registrar

WOOLWICH POLYTECHNIC

LONDON, S E 18

Principal: J S Tait, Ph D, B Sc, A.R T.C., M I.E.E., A.M I.Mech.E

Applications are invited from honours graduates and from students entering for their final honours (special) degree examination in June next for Research Assistantships in Chemistry. The assistantships will normally lead to the Ph D degree (Internal) of the University of London. Their value is £350 per annum and are tenable for two to three years.

Particulars and application form from Clerk to Governors

DEPARTMENT OF SCIENTIFIC AND INdustrial Research requires Scientific Officers at Chemical Research Laboratory, Teddington, Middlesex, 1 (a) Senior S O. with three years' postgraduate experience in chemical engineering or similar work (Ref.: F 929/5) and (b) S O, chemical engineer or physical chemist (F 930/5), for research in a new section. 2 S.O., physical chemist (Ref: F.931/5). Qualifications: first- or second-class honours degree or equivalent. Inclusive annual salary. Senior S.O. · £1,155 to £1,344; S.O £554 to £999. Somewhat less for women but subject to improvement under the equal pay scheme.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting appropriate reference.

FOREMAN OF THE ROYAL GREENWICH Observatory, Herstmonceux, Sussex. The Civil Service Commissioners invite applications from men for this pensionable post Age at least 28 on January 1, 1956. Candidates must have served an apprenticeship or received equivalent training as instrument mechanics, followed by at least three years' experience on relevant work. They must also be thoroughly familiar with modern workshop methods and be able to plan and direct the work of laboratory mechanics O N C. in mechanical engineering or equivalent qualification, and experience in a drawing office or of supervision of instrument work advantageous. Starting salary according to age from £650 (at age 28) to £690 (at 30 or over) Maximum of salary scale is £812 An official residence is provided at a reasonable rent.—Further particulars and application form from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No. S 4563/56/8. Completed applications must be returned by March 29, 1956

ADMIRALTY

CIVIL HYDROGRAPHIC OFFICER

The Civil Service Commissioners invite applications for 5 pensionable posts. Age at least 21 and under 31 on January 1, 1956, with extension for regular service in H.M Forces. Candidates must have an honours degree, preferably first- or second-class, in either geography, mathematics, physics, engineering, geology or kindred subject. All candidates must have passed in mathematics at not less than credit standard in the school certificate or "O" level at the general certificate of education. A reading knowledge of one or more foreign languages an advantage Inclusive London salary scale. £513 to £1,245 (women to £1,155 but being increased under equal pay scheme.) Starting pay may be increased for approved postgraduate experience and for National Service in H M Forces. • Promotion prospects

Further particulars and application forms from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No S217/56/8. Completed applications must be returned by March 16, 1956.

UNIVERSITY OF GLASGOW

LECTURESHIP IN EXPERIMENTAL PHARMACOLOGY

Applications are invited for the whole-time academic post of Lecturer in Experimental Pharmacology. Salary scale: £700 to £1,450 with a medical qualification, £650 to £1,350 without a medical qualification. Initial salary according to experience and qualifications. F S.S U. and family allowance benefits.

Applications (6 copies) should be lodged, not later than March 17, 1956, with the undersigned, from whom further particulars may be obtained.

ROBT. T HUTCHESON,
Secretary of University Court.

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Lecturer in the Department of Fluid Mechanics, at an initial salary within the range £650 to £1,350 per annum, according to qualifications and experience.

Applications, stating age, academic qualifications and experience, together with the names of three referees, should be received not later than March 29, 1956, by the undersigned, from whom further particulars of the conditions of appointment may be obtained

STANLEY, DUMBELL,
Registrar.

UNIVERSITY OF ABERDEEN

Applications are invited for Lectureship in Biological Chemistry. Salary scale (c) £1,350 by £50 to £1,550 (or scale (b) £950 by £50 to £1,350), or if medically qualified scale (c) £1,750 by £100 to £2,050 (or scale (b) £1,200 by £125 to £1,700), with placing according to qualifications Superannuation (F.S.S U) and children's allowance. Part of removal expenses refunded

Conditions of appointment and forms of application should be obtained from the Secretary, The University, Aberdeen, with whom applications (eight copies), giving the names of three referees, should be lodged not later than March 24, 1956. Applicants outside the British Isles may submit one copy only.

THE INTERNATIONAL GEOPHYSICAL YEAR

A circular containing the details of 43 vacant posts in connexion with the United Kingdom programme for the International Geophysical Year has been circulated to University Appointments Boards and other University Departments.

Persons who are not able to inspect those copies may obtain further details on application to the Assistant Secretary, The Royal Society, Burlington House, Piccadilly, London, W 1.

ADMIRALTY—ROYAL NAVAL SCIENtific Service Senior Scientific Officers and Scientific Officers required in Experimental Establishments chiefly in Weymouth and Portsmouth areas and home counties Majority of posts are for engineers and physicists (particularly with electronics) Candidates must normally be natural born British subjects of natural born British parents, with appropriate first- or second-class honours degree or equivalent high professional attainments. Salaries (men), Senior Scientific Officer £1,070 to £1,245; Scientific Officer £513 to £925 (London) Somewhat lower in provinces All appointments unestablished (with F S.S U) but with some opportunities to compete for established posts.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W.1, quoting A344/5A.

COMMONWEALTH of AUSTRALI

DEPARTMENT OF SUPPLY
DEFENCE STANDARDS LABORATORIES
MARIBYRNONG, VICTORIA

Applications are invited for a temporary pos tion of Senior Scientific Officer at the abov Laboratories Salary: £2,053 to £2,218 p annum Duties. Research and development wo in connection with paints, such as the study methods of measuring the properties of paint fil and changes in properties during ageing a weathering, the study of the protection of meta by primers, underwater protection of ships a anti-fouling paints. Qualifications: Degree high standard with chemistry as a major subje with several years' research experience Knowledge of paint technology would be an advanta The salaries quoted are Australian currenc Whilst the position is a temporary one, the tenu of employment is not limited. However, the su cessful applicant may choose to enter into agreement for a three to five year contract of e ployment in Australia. In this case, the Co monwealth will bear return fares, together wi cost of removing each way the appointee's fur ture and effects up to a maximum cost of £5 (Australian) (£250 (A.) each way) Under specifi conditions, first-class boat fares (if first-class ber available) for the appointee and dependants (wi and dependent children) will be paid by the Commonwealth.

Application forms obtainable from Senior Re resentative (AP 45), Department of Supp Australia House, Strand, London, W C 2, wi whom applications should be lodged by Mar 19, 1956.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH

NEW DELHI

Applications invited for post of Director, Ce tral Electronics Engineering Research Institut Pilani (Rajasthan), within salary range £1,800 t £2,250 per annum. Applicants must have a hi degree in applied physics and experience in circu techniques, equipment design, and in directi industrial research programmes. Appointment o contract 3 or 5 years.

Further information and application forms fro High Commission of India, London, W.C 2, refe ence Est.201 1.4/99. Last date for receipt of a plications in India is March 15, 1956.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for a Lectureship i Chemical Engineering. Salary on the scale £65 by £50 to £1,350 per annum; the initial sala will be fixed according to qualifications and e perience, but will not be more than £1,000 p annum. F.S.S U. benefits and family allowance

Further particulars may be obtained from th Registrar, University College, Singleton Par Swansea, to whom applications must be sent b March 17, 1956

UNIVERSITY OF LEEDS

DEPARTMENT OF MATHEMATICS

Applications are invited for appointment a Lecturer or Assistant Lecturer in Statistics at salary on the scale £650 by £50 to £1,350 a yea for a Lecturer or within the range £550 to £65 a year for an Assistant Lecturer, according t age, qualifications and experience

Applications (four copies), stating date of bir qualifications and experience, together with th names of three referees, should reach the Regi trar, The University, Leeds, 2 (from whom fu ther particulars may be obtained), not later tha April 2, 1956.

SCIENTIST REQUIRED IN MEDICA Statistics Section at N C.B.'s London H Q, a member of a team concerned with statistica planning of field and clinical trials on medical an cognate problems, and analysis of results, als collection, presentation and analysis of statistic relating to health of mineworkers. Degree i mathematics, or recognized qualification in statis tics required, postgraduate experience in applyin statistical methods (including knowledge o punched cards) an advantage. Appointmen (superannuable), according to qualifications an experience, as Scientist 3 (inclusive scale £617 t £1,124 male)—Write, with full particulars of ag education, qualifications and experience, t National Coal Board, Staff Dept. (Personne Hobart House, Grosvenor Place, S W.1, marking envelope SS/219, before March 20, 1956

SCIENTIFIC OFFICER (CHEMIST), ASSISTant Experimental Officer (Chemist), and an Assistant (Scientific) in the Metropolitan Police Laboratory.—The Secretary, Room 165, New Scotlan Yard, London, S W 1

TECHNOLOGICAL HUMANISM

THE 1955 conference of the Scottish Institute of Adult Education, which was held at Dunblane, provided Sir Eric Ashby with another opportunity to continue his inquiry into the malaise which seems to afflict adult education in Great Britain (*Scottish Adult Education*, No. 15; December 1955). It can be read with profit during the discussion of the White Paper on Technical Education in Britain just issued (see p. 461).

Adult education, he suggested, is in a dilemma of ends and means. There is, of course, a vague end in view. Although education for leisure and for personal satisfaction is now declared to be the purpose of adult education, it is a very shadowy purpose compared with that of (say) a Workers Educational Association class of forty years ago. That class was an instrument to secure social and political emancipation. Its purpose was vocational in the highest sense of the word: it was for men who believed they had a vocation. The ends were clear, but the means were on the whole inadequate for the ends. Now the means have become more adequate, but the ends have become clouded.

It is misleading to make an issue of differences between technical and cultural education. Some of our perplexities in universities, technical colleges, and further education have their origin in the antithesis which has been set up between these two groups of ideas and the consequent controversies over what should be the balance between them. A distinction between vocational and non-vocational education can be made; it is questionable whether it is worth making.

To-day a gifted man cannot play his part in society unless he is something of a specialist. Instead of fighting a rearguard action on behalf of general education against specialization, is it not more important to consider whether the benefits of humanism cannot be acquired through, and not in spite of, specialization?

Sir Eric went on to discuss whether a new concept of liberal education is desirable; and, what the new concept and interpretation should be.

One must start with the sound academic maxim that no change is desirable for its own sake; that change is justified only if there is pressure due to other uncontrollable changes which have already occurred, or in anticipation of such uncontrollable changes. In Britain personal education enjoys the greatest prestige, despite all that is being done in the way of technical education and education for economic ends. Personal education is the keynote of grammar schools, it is the traditional function of the arts faculties of universities, and it is by Government regulation defined as that part of further education called liberal adult education.

Is this emphasis on personal education consistent with the present state of Western society? The world has changed out of all recognition, and accompanying these changes there are new anxieties.

These changes have two consequences. There is a new preoccupation with resources; people worry about food, about new forms of energy, about new materials; and there is a phrenetic concern for security—secure jobs, secure status in the community, national security. Society is again living dangerously and spends most of its time thinking about means and not ends.

Do these great social changes justify a change in the concept of liberal education, a re-examination of humanism? No one would assert that the old literae humaniores are reaching the bloodstream of modern civilization. That is the problem which frustrates educators; not that the old humanism has become outmoded but that it has become impotent.

We are entering a civilization of experts and technicians. The humanism appropriate to such a civilization must be one that confers values on the automatic factory, the aeroplane, television, and the popular Press; it must have something to offer the sort of man who a century ago could neither read nor write, and who now reads only the popular Press and listens to the Light Programme of the B.B.C. For these reasons there should be a re-interpretation of humanism, and the purpose of liberal education should be to transmit this re-interpretation, which must, of course, embody the imperishable elements of earlier humanisms. Sir Eric declared his belief that the missionaries of the new humanism would not be in schools but in adult education.

As a basis for humanism, science has one insurmountable disqualification. It is of the essence of the scientific method that the human element must be eliminated. Science does not dispense with values but it does eliminate the variety of human response to values. It is concerned only with phenomena upon which all qualified observers agree. Its whole energy is devoted to describing, measuring and classifying natural phenomena in such a way as to secure agreement among all men; and this can be done only by making its values independent of man. The whole procedure of the scientist assumes that science has to be dehumanized.

Scientific humanism should therefore be ruled out as an alternative to classical humanism. There is another alternative which could be called technological humanism. The unique characteristic of our age is not the scientific way of thinking but the bewildering way in which the applications of science to society have shaken the foundations on which society has stood for centuries, and have raised not simply economic issues but also moral and ethical issues. Chemotherapy and preventive medicine, for example, have enormously altered the pattern of family life. The applications of science to industry have already created a problem of the mass production of leisure. The aeroplane and the radio have devalued the classical methods of diplomacy.

Is it not essential that liberal education should include an understanding of the social and moral consequences of technology and should concentrate upon the re-interpretation of the old values in such a way as to make them relevant to the new civilization which is upon us ?

This is not the only justification for the study of technology as part of a liberal education. The greater justification is that in the broad study of technology there are many of the ingredients which have for centuries been associated with a liberal education. Technological humanism could preserve the best of the traditional humanism: it could be catholic and continuous with the past; and at the same time it could enter the bloodstream of modern society, which the old humanism fails to do.

Technology concerns itself with the creative acts of man. To enthuse about Gothic churches and Tudor town halls and not even to glance at Viscount aeroplanes and stressed concrete bridges cannot be justified on the grounds that only the former are creative arts of man. It is simply an unwillingness to face the present.

Technology has its own standards of excellence and taste. A lot is talked about the shoddiness of mass-produced articles; fibre suit-cases compared with hand-made leather ones, gimcrack furniture compared with Chippendale. This is a weakness inherent in the public who accept these articles and not in technology. Where standards are insisted upon (as in aeroplanes, cameras, or gold watches) there is excellence. The lesson that good design is not necessarily expensive has not yet been learned. The establishment of standards for taste is an essential ingredient of technology.

Technology involves the handling of ideas and the establishing of values. In brewing, for example, there are many abstract ideas which are encountered by a man who wants to master its technology. There are the purely scientific ideas of microbiology, and there is the craft of the structural engineer who designs brewing plant. The beer has to be marketed; mass psychology, the education of public taste, diplomacy, or power politics in dealing with other brewers—all these are needed. This compels the brewer to become interested in tied public houses and hence in the architecture of public houses. If he has a mind receptive of liberal ideas he will be troubled by at least two moral problems. On one hand, he may feel under a moral obligation to put into his tied houses interesting pictures or good music. On the other hand, he could not reflect long on his job without facing the problem of the dangers of excessive drinking, and his responsibility for it; and to deal with these questions takes him into ethics and even religion.

Technology offers social coherence. One function of a liberal education is to endow people with a common heritage. In the past, technology has not been an instrument of coherence but rather of disruption. Is it not possible that technological humanism could change that ? Could the machine not be made a cement between the manager and the worker, the administrator and the employee? If both sides shared a common appreciation of machines and their function, they would become part of a common heritage. Technological humanism might achieve this end. If these ideas are pursued along the path of technology as well as along the older paths of literature, a greater number of students will acquire a liberal education, and those who take this particular path are likely to have a great influence on mass communication and propaganda, which will set the cultural standards of the bulk of the people.

EARLY HISTORY OF THE SURVEY OF INDIA

Historical Records of the Survey of India
Volume III, 1815 to 1830. Collected and compiled by Colonel R. H. Phillimore. Pp. xxii+534, and 19 coloured maps. (Dehra Dun, U.P.: Geodetic Branch of the Survey of India, 1954.) Rs. 20 or 31*s*.

THIS is the third of Colonel R. H. Phillimore's projected five volumes of "Historical Records of the Survey of India", covering the period before 1861 when annual reports were first published. The present volume takes the story from 1815 to 1830, when Everest took over both as superintendent of the Great Trigonometrical Survey and as surveyor-general of India. The period is one of great technical interest, and during it the foundations were laid or consolidated of many of the activities on which the future reputation of the Survey of India was to rest.

The arrangement is the same as in previous volumes. An introductory chapter gives a brief outline of the chief events of the period, and this is followed by detailed accounts of topographical and revenue surveys in the various provinces. Chapters are also devoted to astronomical control, the Great Trigonometrical Survey, professional details, and instruments, maps, administration, pay and allowances and personnel. Biographical notes on the principal characters take up more than a hundred pages, and there is a very comprehensive index. The narrative consists largely of extracts from the correspondence of the main characters in the story. Though this does not make for easy reading, it gives the reader an insight into the characters of the writers and the conditions in which they lived, which would otherwise be hard to convey. The advantages of the method thus more than compensate for any extra trouble in reading.

Probably the most important and far-reaching decision of the period was the recognition of the Great Trigonometrical Survey as the only sure foundation for all survey work and the priority given to it by Blacker when surveyor-general. By 1815 Lambton had extended his triangulation from southern India to Hyderabad, but he was now an old and sick man. Fortunately for the future of surveying in India, the youthful Everest joined as his assistant about three years before his death in 1823, thus ensuring continuity of his ideas and methods.

During the period, the plane-table gained ground rapidly as the main instrument for topographical surveying. It is not clear from this volume whether the method of three-point resection was then in use; and it seems possible that some of the prejudice against the plane-table was due to the earlier and unreliable method of orientation by compass, and resection from only two fixed points. Prior to 1828, Indians were only employed on revenue surveys, largely on security grounds. In that year, however, the first Indians were trained in plane-table surveying. They thus became the forerunners of that large and distinguished company of Indian surveyors whose skilled use of the plane-table was to make possible the cheap and rapid surveys which during the next hundred years covered a large part of central and southern Asia.

Geographically perhaps, one of the most interesting discoveries of the period was the heights of many of the main Himalayan peaks in the Garhwal–Kumaon region. These were so unexpectedly great that they were at first received with incredulity by the scientists of Europe. Other important geographical discoveries followed the opening of the Assam valley in 1824. This enabled the surrounding hills to be explored and opened the way for the first investigations into the identity of the Brahmaputra and Dihang Rivers with the lower reaches of the Tsangpo.

On the mapping side there was the initiation of the "Atlas of India" in 1822. This was designed to cover the whole country with maps on the scale of a quarter of an inch to the mile on a standard layout. After some uncertainty as to who should do the work, the Court of Directors laid down that the compilation and engraving should be done in Britain from material sent from India. Perhaps this decision was inevitable at the time; but few nowadays would deny that maps from original surveys are best compiled by those with first-hand knowledge of the areas concerned. The establishment of lithographic printing in India at about the same time was another great step forward in the popularization of maps. Hitherto they had been copied by hand from the original compilations, so that few maps were available for distribution; but shortly after the introduction of lithographic printing, the publication of maps for sale in quantity was started.

The production of this volume maintains the high standard of previous ones, and the beautifully reproduced maps and sketches leave the reader with a great respect for the artistic abilities of the early surveyors. Thanks are due to the Government of India for the support which has enabled Colonel Phillimore, in spite of all the changes during recent years, to carry on his great work begun on his retirement from the Survey of India more than twenty years ago. The preparation of the remaining two volumes is already well advanced, and it is to be hoped that they will be published in the not too distant future.

G. F. Heaney

LIVING MAMMALS

Living Mammals of the World

By Ivan T. Sanderson. Pp. 303 (330 illustrations). (London: Hamish Hamilton, Ltd., 1955.) 63*s*.

The publishers claim that this book "is an authoritative reference work" which will "in the words of a leading zoologist, 'fill a very important place in the literature of the subject and become a classic for many years to come'". This suggests a high standard of accuracy. The illustrations are said to be "extraordinary" and "many of them were taken in the wild". The author himself states that his main object is to describe the mammals adequately enough for the layman to be able to identify them on sight.

A well-produced and lavishly illustrated volume such as this will appeal to many who will be unaware that it falls very far short indeed of both the publisher's claim and the author's intention. The general plan is based on Simpson's 1945 classification from orders downwards. Most of the subject headings refer only to the subfamily or genus, after the popular name for the group, and very few species are identified by their scientific names. No doubt this reduces technicalities; but the result is a general vagueness, since the reader is often quite uncertain which species of a genus is being discussed. Some large groups of small mammals are dismissed in a few lines on the plea that it is quite impossible to describe them in a limited space.

The standards of accuracy are frequently low. Whether in the form of wild exaggeration, contradictions, taxonomic confusion, unreliable distributional data, surprising colour descriptions, or just unfounded statements of all kinds, mistakes abound to such an extent that it is quite impossible to recommend this book. Space permits of only a few typical examples.

The largest African dormouse is said (p. 128) to be two feet long. The largest specimen I have seen is 12 in. long overall. The masked civet, *Paguma* (p. 170), is said to be nearly four feet long with a tail of equal length. The largest I have measured is 4 ft. 4 in. overall. The ears of the false vampires (*Megadermatidae*) (p. 59) are described as twenty times the size of the head. In the largest I can find, *Macroderma gigas*, the head is 40 mm. long and 20 mm. wide, the ears are 50 mm. long and 65 mm. wide together. The elongated ankle bone of the tarsier (p. 69) is said to be longer than either the thigh or the calf [*sic*]. Actually it is shorter than either femur or tibia. We are told that the squirrel monkey (*Saimiri*) (p. 74) on reaching full maturity may be four times the size of the average adult—a remarkable statement.

Some whales are said (p. 210), while travelling at more than twenty knots ahead of a ship, to dart ahead and "vanish in a second". We are told (p. 204) that more than one of the author's captive grisons "literally burst through overeating". We also learn that two small, short-legged mammals, the brush-tailed porcupine (p. 147) and the armadillo (p. 110), are among the fastest animals on all fours. We read (p. 49) that the hedgehog when alarmed leaps into the air with all four feet to drive its spines into an attacker. The habitually solitary leopard seal is described (p. 158) as migrating "in enormous crowds".

There is often remarkable confusion in taxonomy. The specific epithets of the tamandua (p. 105) and the pygmy anteater (p. 106) are used generically (thus *Tetradactylus* and *Didactylus*). In an attempt to explain the use of the generic name *Panthera* for the great cats, and at the same time to clear up the popular confusion of the terms leopard and panther, Sanderson actually says (p. 162) "all the Great Cats that can roar are now officially *panthers* [author's italics] as the technical name implies". Under the heading Sokhors (*Myospalax*) (p. 122), which is a specialized Chinese rodent forming a separate subfamily, we find a recognizable description of an Indian mole-vole (identified beyond doubt by reference to the Quetta 'mole') of the genus *Ellobius*, a microtine referred to by name on p. 124. There is complete confusion over African otters (pp. 208–209). The spot-necked otter (*Lutra maculicollis*) is described under the name *Paraonyx*, a very different animal, after the statement that *Lutra* does not occur in

Africa. Under hartebeestes (p. 263), having started with Cooke's [*sic*] hartebeeste, we are told at the end of the section "One species is known as the Kongoni". This is, of course, the common name of Coke's hartebeeste!

Some remarkable errors of distribution occur. The grey seal (p. 158), "a shy lone animal", is said to occur no farther south than south Scotland. Both statements will interest those who have studied colonies on the coasts of England and Wales. On p. 162 we learn that the snow leopard is found in Amurland and Sakhalin Island, even down to sea-level in winter. The actual range is the Central Asian mountain region, reports from elsewhere being almost certainly due to confusion with local leopards. We are told that the African zorille (p. 205) is found in North Africa, Egypt, North Arabia, Palestine, Syria, Asia Minor and around Constantinople. In fact, there are no records for any of these areas, and the recognized northern limit is the Sudan. Among the seals, the Hawaiian seal of the mid-Pacific is ignored (pp. 155 and 158), the presence of a hitherto unknown seal in the Indian Ocean is reported (p. 158), but unfortunately without any data, and the distribution, as well as the taxonomy, of the Otariidae is thoroughly confused.

There are many other errors, but only a few can be cited here. The New Guinea three-toed spiny anteater (p. 16) is said to have a naked grey skin; it is actually thickly coated with dense black fur almost hiding the spines. On p. 55 an attempt is made to explain the principle of echo-location in bats; "supersonic" is used for ultrasonic, and the confusion of pitch (vibration frequency) with duration of sound results in complete inaccuracy. The naked bulldog bat (*Cheiromeles*) (p. 62) is said to have a pouch in the skin of the neck "in which the female carries her young". Its occurrence in the male is said to provide for the possibility of twins. But this sac is actually a very small and shallow scent gland structure. What Sanderson does not refer to is a roomy pouch at the junction of the wing membrane with the body, formerly thought by some writers to be for the transport of young, but recently shown to be a sheath for the folded wing tip at rest. The account of the habits of lions (p. 161) has little relation to fact; lions are not terrified of children, they do normally kill more often than once a month, and when not hunting they are not in the habit of "lying down back-to-back with the antelopes". The Bornean civet *Diplogale* (p. 171) is uniformly dark brown, not spotted. Palæontologists will learn with interest that the unfossilized bones of a carnivorous ungulate, the Chalcicothere [*sic*], are found in the soils of East Africa, and that this animal may be the dreaded Nandi bear. Finally, to get the record straight (a favourite phrase of Sanderson's) it should be mentioned that the 11 ft. 5 in. African elephant tusk (p. 293) does *not* weigh 293 lb. It is one of a pair the *combined* weight of which is that figure. The heaviest known tusk is 226½ lb.

Many descriptions indicate that the author has his own colour standards, and in many of the coloured plates the subjects appear to be bathed in the after-glow of a lurid sunset. Plate 98 of a lion is quite unrepresentative of the animal, both in its colour and since it is so obviously a menagerie specimen. Several of the illustrations (many of them old friends) are wrongly titled. On p. 170 the "small-toothed palm civet, *Arctogalidia*", is actually a Burmese palm civet, *Paradoxurus*. Darling's mole rat (p. 127) is a *Cryptomys*, not a *Spalax*. Plate 97 labelled grey seal is a common seal. The illustration on p. 159 is of a male elephant seal, not a female (despite the pup). Plate 146 is a warthog, not a giant forest hog, and Plate 181 shows impala, not Grant's gazelles. Less than 10 per cent of the pictures were taken in the wild; the rest are zoo animals, often posed in artificial surroundings.

Misspellings of scientific names are frequent.

I take no pleasure in directing attention to the many failings of this work, but since quite unfounded claims have been made for it I feel that the opportunity should be taken "to get the record straight". One might almost apply to this book Sanderson's own description of Melville's 'Moby Dick' (in connexion with sperm whales)—"a work of magnificent imagination and almost total zoological inaccuracy".

R. W. Hayman

TALKING ABOUT COMMUNICATION

Studies in Communication contributed to the Communication Research Centre, University College, London

By A. J. Ayer, J. B. S. Haldane, Colin Cherry, Sir Geoffrey Vickers, D. B. Fry, J. Z. Young, R. Wittkower, T. B. L. Webster and Randolph Quirk. Pp. vii+182+9 plates. (London: Martin Secker and Warburg, 1955.) 21*s*. net.

"If we are to take a hand in developing this process of communication," says Sir Geoffrey Vickers, "we must be able to talk about it; and at present we are ill-equipped to do so. . . . For the underlying issues are screened from us by what is itself a failure of communication. We have no language in which to discuss them with each other; and hence no concepts with which to present them to ourselves." The issues are screened from us, true. But they are screened not by the lack of language and concepts. They are screened by 'Babel'. This volume adds entertainingly and provocatively to the Babel. To be positively and contemporaneously correct, one should call it Meta-Babel.

The reader is given a two-dimensional *hors d'œuvres*: a dozen varieties of meaning of the word 'communication', and at least half a dozen different terminologies in which to discuss them—biological, cybernetic, administrative, neurological, æsthetic, linguistic. The terminology to end all terminologies is provided by the inevitable Prof. A. J. Ayer when he remarks: "It will be seen that there is something here for almost everyone". Prof. Ayer always says many sensible things, but one is never quite sure why he is saying one set of sensible things rather than another; and this sums up one's bewilderment about the book as a whole. One is also bewildered at the extent to which analogy and metaphor are being exploited in this new subject, if it is a subject, of communication. Thus Prof. J. B. S. Haldane writes that "Fruits signal to insects by colour" and also "Fruits advertise themselves to be eaten by mammals and birds". But perhaps these are not intended as metaphors, for he says: "A very large part of biology can be looked at from the point of view of communication theory".

Can communication theory provide a unifying language for the problems of communication?

According to Dr. Colin Cherry (who should know), the "measure of information" of Shannon and Wiener "has nothing whatever to do with meaning, nor with value, nor with usefulness of messages". There seems to be a contradiction here. Prof. J. Z. Young pinpoints the contradiction by saying that "what we still need is a greater unification of our approaches", but "The essence of the scientific approach is the realization that for each purpose we should use a different analogy". Prof. Ayer might have reminded us of the old problem of "the one and the many".

Those of us who enjoyed the hospitality of University College, London, and the stimulus of the oral delivery of these papers, will be glad to have this volume as a record. But a reviewer has a duty to appraise fulfilment of purpose. This is the first publication of the Communications Research Centre—"a first fruit of its activities" says the jacket. These individual essays doubtless contribute to the clarification of the problems of the Centre, and, in their several ways, they make excellent reading; but as a first publication of a research centre this volume puts remarkably little new research on record. This criticism is offered in no captious spirit. All who are alive to the vital importance of communication must have welcomed the establishment of the Centre. One cannot help asking whether this volume is the kind of publication which testifies to the serious research-intent of the Centre, or really furthers its object.

G. PATRICK MEREDITH

PROGRESS IN BIOPHYSICS AND BIOPHYSICAL CHEMISTRY

Progress in Biophysics and Biophysical Chemistry

Edited by Prof. J. A. V. Butler and Prof. J. T. Randall. Vol. 5. (Progress Series.) Pp. viii+231+9 plates. (London and New York: Pergamon Press, Ltd., 1955.) 55*s*. net.

THIS volume opens with a review of the reaction patterns of a coliform organism, by A. C. R. Dean and C. N. Hinshelwood. The application of kinetic principles to cellular growth, and the action of enzymes concerned therein, are lucidly surveyed and related to many different processes, of which adaptation and mutation may be mentioned. In their consideration of the physical chemistry of hæmolysis and bacteriolysis by surface-active agents and antibiotics, J. H. Schulman, B. A. Pethica, A. V. Few and M. R. J. Salton are also concerned with the application of physical chemistry to living organisms, particularly microbes. The fact that the enzyme lysozyme brings about a specific depolymerization of the cell walls of certain organisms has resulted in the preparation of protoplasts which, although deprived of cell walls, are capable of metabolizing glucose at the same rate as intact cells. It is clear that the investigation of the unclothed protoplast is likely to be of special value in research on the mechanism of action of substances which influence cellular metabolism.

For obvious reasons, the direct action of ionizing radiation on enzymes and antigens, as discussed by E. C. Pollard, W. R. Guild, F. Hutchinson and R. B. Setlow, is a matter for particular current interest, while for quite another reason the structure and function of the chloroplast (J. B. Thomas) can be of practical interest in a world looking for new sources of energy, of which sunlight is an obvious one for consideration. The theory of X-ray fibre diagrams (A. R. Stokes) is always a subject of some difficulty for the non-specialist, but the discussion given in this book is one that can be followed in general without great difficulty by those not carrying out research in this field. The last contribution in the volume is on recent studies on the reversible denaturation of proteins, by M. Joly It is natural that Dr. Joly should spend more than two pages discussing possible definitions of protein denaturation and then fail to adopt any simple definition. His ultimate conclusion, that in spite of a certain similarity between all the observed phenomena there exist several types of denaturation and reversal depending on the protein considered and the denaturing agent used, is not unexpected. But it is most desirable that this rather ill-defined state should be discussed and, together with the means whereby it can be brought about, considered in the light of present knowledge of protein structure; this Dr. Joly has attempted to do with some success. It is most unfortunate that the 252 references to the original literature cited by him have been omitted from the main index of this volume owing to an oversight on the part of the publishers. It might have been better to have re-set the index and to have delayed the appearance of the book rather than to publish it with an incomplete index.

This volume adds one more to the many books in related fields which now appear annually and include in their title either the word 'advances' or 'progress'. None of the subjects surveyed in this volume is ineligible for consideration in one of the other annual review volumes; but for those whose special interest is in the application of physical methods to biological problems, there is undoubtedly an advantage in having this collection of articles within the covers of one book.

F. G. YOUNG

THE INSTITUTE OF BREWING

A History of the Institute of Brewing

By W. H. Bird. Pp. ix+139+16 plates. (London: Institute of Brewing, 1955.) n.p.

THE author, who was secretary of the Institute of Brewing until 1951, has produced an interesting and informative book. In 1886, Dr. E. R. Moritz, consulting chemist in brewing, was in the habit of holding informal colloquia; these crystallized into the "Laboratory Club", which published transactions and by 1890 had 250 members. Similar bodies were formed elsewhere, and in 1895 all were federated and later (1903) merged into one—the Institute of Brewing. During 1895–1903 the *Journal* represented its main activity; but further projects were under consideration. The Midland Counties Institute favoured setting up a school of brewing. Agreement was not forthcoming; but the Midland brewers attained their object independently, and the British School of Malting and Brewing at the University of Birmingham resulted (1900).

The essential objects of the Institute of Brewing were defined as the promotion of such sciences and arts as are of practical application to brewing and allied industries, and the dissemination of knowledge useful in such connexion. The whole of the technical personnel of these industries were eligible for membership. Six sections (now also one in Australia) held monthly meetings. In due course committees were set up to advise on examinations, analysis and, later, research (1918). Since 1922 the Institute has conducted examinations annually on subjects ranging from fundamental physics and chemistry to brewing technologies, engineering, etc.

The research scheme has passed through three phases. At first, problems were investigated in various places by workers maintained there by the Institute: barley at Rothamsted, hops at Wye (new varieties), growing, etc., at East Malling, and the antiseptic constituents at the Manchester College of Technology, nitrogen metabolism of yeast at the Imperial College of Science and Technology, London, and Cadby Hall (J. Lyons and Co., Ltd.), and *p*H in relation to brewing at W. Younger's and Tetley's breweries. At this time a research organizer co-ordinated the work. In 1934 all laboratory work except that on hops was concentrated in the Birmingham Brewing School, all the studies being supervised by committees already in being. Finally, after many setbacks, a director was appointed, and all the work was transferred to the present Brewing Industry Research Foundation at Nutfield (1951). This is still the Institute's research scheme, financed on a vastly greater scale.

During the Second World War, contributions to the national effort included experimental work on the use of oats, flaked barley, lupulin, surplus yeast, concentration of beer, pest infestation of barley and vitamins of the B group in beer. A final contribution to brewing science and education has been the Institute's membership and support of the European Brewery Convention (1947).

The book has eight appendixes recording the names of officers of the Institute and forty-nine photographs of some of these and of scientists who have contributed to its success. The index is very comprehensive.

R. H. HOPKINS

RESEARCH ON TUBERCULOSIS AND LEPROSY

Experimental Tuberculosis

Bacillus and Host. With an Addendum on Leprosy. Edited by G. E. W. Wolstenholme and Margaret P. Cameron. (A Ciba Foundation Symposium.) Pp. xii+396+24 plates. (London: J. and A. Churchill, Ltd., 1955.) 42*s*. net.

PRESENT-DAY research in tuberculosis and leprosy continues to attract investigators of widely different disciplines, each interested basically in a limited aspect of the subject regarded from his own scientific point of view. There is thus a danger of the study of these important diseases becoming fragmented into entirely separate domains of chemistry, pharmacology, pathology, bacteriology and immunology. One of the most valuable contributions of the Ciba Foundation is its rare facility for organizing symposia in which all these separate approaches to what is fundamentally one coherent study can be blended. Reports which would normally be heard only by workers of the same scientific background are here presented in an informal atmosphere for consideration by those equally expert in other branches of the selected subject. Thus, in the published symposia, the most striking feature is not the undoubted excellence of the main contributions, but the unusually stimulating discussion on each paper, which is reported verbatim. In a symposium of this type there is far less preoccupation with specialized knowledge than is usual at any sectional meeting; the exchange of ideas, and the cross-fertilization of one speciality by another gain considerably in the process.

The present symposium begins with a series of papers on the chemical structure of Mycobacteria and the biological activity of various fractions of the bacterial protoplasm. The emphasis here may seem perhaps a little overwhelmingly academic to the medical research worker. However, a very large volume of work is skilfully compressed into short readable accounts, and the implications and objects of the researches are well brought out both in the discussions and in the well-balanced progress of the programme. In the next section attention is gradually focused on the host animal—how the tissues respond to the infecting organism, and which bacterial fractions are important in eliciting such response. Here both hypersensitivity and immune reactions are considered. Equally important is a complementary study of how the bacilli themselves may be affected by biochemical reactions of the host animal. Some of the factors concerned in resistance to infection are illustrated by *in vitro* studies with infected tissue cultures, and by observations of the immunity of animals previously exposed to non-lethal infections; indirect evidence obtained by interference with the normal host–parasite relationship by cortisone or by chemotherapy is also presented. In the addendum on experimental leprosy, the common denominators in the two diseases and in the tissue responses of the infected host to either organism are underlined.

In a symposium of this size, it is perhaps invidious to select individual contributors for special mention. It suffices to say that, whatever the special interest of the reader, here he will find his acknowledged leaders; however well he considers he 'knows the literature', he will still learn much from reading each contributor undergoing the only satisfactory test—trial by his peers.

DEREK HOBSON

METEOROLOGY OF THE FALKLAND ISLANDS AND DEPENDENCIES

The Meteorology of The Falkland Islands and Dependencies

By J. Pepper. Pp. vi+249. (London: Crown Agents for Oversea Governments and Administrations, 1954.) 42*s*.

THIS large, beautifully produced book contains a discussion and tabulated summaries of the surface meteorological observations made between 1944 and 1950 at Port Stanley, Falkland Islands, and at nine stations in the Dependencies constituted by the Graham Land Peninsula on the Antarctic Continent and the islands in the Antarctic Ocean to the north of Graham Land. The station farthest south, Marguerite Bay on Graham Land, is some nine hundred miles from Port Stanley. All are at or near sea-level. Besides meteorological data, the book includes a description of the sea–ice variations observed in 1950.

The Dependencies stations, except for the one at South Georgia operated by an Argentine whaling company until 1949, were originally set up by the

Royal Navy in 1943–44, and since 1950 they have formed part of the Falkland Islands Dependencies Survey Meteorological Service, which has its headquarters at Port Stanley and performs all the usual functions of a meteorological service, including weather forecasting. The book, which was prepared in the Climatological Division of the Meteorological Office, is in three parts: a general discussion, written by Dr. J. Pepper; a gazetteer of stations; and climatic tables.

The publications of the meteorological work on Antarctic expeditions include some of the classics of meteorology but, on the whole, they are restricted in time and space. This is the first publication to survey the weather of a large area of the Antarctic for so long a period. The weather of the area is controlled by the continual passage of depressions and the intervening ridges of high pressure; and so it is very changeable, with relatively small seasonal variations but large changes associated with the passage of fronts. Mean pressure is low—about 900 mb. at the Dependencies and 1,000 mb. at the Falklands. Mean monthly temperature varies between about 35° F. in summer and 15° F. in winter over the Dependencies, and 48° F. in summer and 35° F. in winter at the Falklands. Rises and falls of temperature of up to 40 deg. F. occur in the Dependencies with the passage of warm and cold fronts respectively. An interesting comparison with northern-hemisphere stations at the similar latitudes and situations (for example, Godthaab in Greenland) shows the Antarctic ones to have warmer winters and cooler summers, demonstrating the more intense circulation of the Antarctic. Interesting details are the very high frequency of visibility exceeding 40 km. and the 'burning' of sunshine cards at solar elevations less than 2°—exemplifying the purity of the air—the observation of iridescent clouds by moonlight, and the exactness with which the rise of temperature in air descending from the 5,000-ft. plateau to Marguerite Bay corresponds to the adiabatic value.

The tables include monthly summaries of all the meteorological elements, and frequency tables for many of them for all the stations. Special praise must be given to the gazetteer, with its photographs and detailed topographical descriptions. It is regrettable that no index is provided.

OPTIMAL SPAN OF WORKING LIFE

Ageing in Industry

An Inquiry based on Figures derived from Census Reports into the Problems of Ageing under the Conditions of Modern Industry. By F. Le Gros Clark and Agnes C. Dunne. Pp. xi+149. (London: The Nuffield Foundation, 1955.) 6s.

THE only people who seem to have solved the problem of their senescent members seem to have been the mythical Hyperboreans whose aged, when they wished to retire from life, performed a "joyful suicide" by decking themselves with garlands and precipitating themselves from a rock into the sea. Non-mythical peoples have found various other solutions. The Tibarini used to hang their old on gibbets, the Hircanians and Bactrians cast them, while still living, to the dogs, and the Scythians buried them alive.

In Great Britain such drastic measures have never been contemplated, although the plight of the aged has often given cause for much distress. During the past two or three decades we have become increasingly conscious of the wider repercussions of our ageing population and the resulting social and economic disadvantages. The highly complex situation was fully examined by the Royal Commission on Population (1949). The Commission's report was particularly concerned with the growing 'burden of dependency', that is, the decline in the proportion of producers per consumer, and it emphasized the desirability of prolonging the productive capacity of workers beyond the age of sixty-five. At that time, however, it was not possible to give anything like a precise answer to the question: "At what ages are men compelled, by reason of their age alone, to leave the occupations in which they have spent their working lives?" This is the important question to which Mr. F. Le Gros Clark and Miss Agnes Dunne address themselves in this book. Their inquiry is based on figures derived from the Census Reports for 1921, 1931 and 1951 and relates to four million men in thirty-two occupations, representing about a quarter of the occupied male population of Britain in 1951. The principal method of analysis employed by them is that of the 'moving cohort'; they have taken a decennial age-group from each of the thirty-two occupations at 1921 and followed it through until 1951.

They define the 'survival-rate' of working men as the proportion of men who reach their mid-sixties in a given job and are physically capable of remaining in it until their late sixties or beyond. The survival-rates for the different occupations range from 75–85 per cent among watch- and clock-makers to 5–15 per cent among workers at the coal face. Agricultural workers and men in certain building trades have relatively high survival-rates as compared, for example, with tobacco workers, compositors, foundrymen, bus conductors and constructional engineers. By appropriately weighting the thirty-two occupations and making allowance for the proportion who would have to cease work because of impaired health, the investigators estimate that alternative jobs would have to be found for 20–30 per cent of those aged 55–64 in 1951. For the country as a whole, this amounts to forty thousand alternative jobs to be found every year over the relevant ten years.

A second analysis shows the ratio of those aged 65 and over to those aged 35–64 in each of the thirty-two occupations. This reveals considerable variation between the occupations in respect of their employment of older men, a variation which suggests an incapacity on the part of many workers to remain in certain occupations under present conditions. In a third analysis the investigators show the changes in age structure of the occupations which took place between 1931 and 1951 in relation to the contraction or expansion of the occupation.

This is a most valuable study which will provide industry, the trade unions and many government departments with much-needed food for thought and perhaps a first guide to action. The authors' efforts will not have been in vain if their report leads at least to serious research into possible alternative jobs for older people and into methods of reducing the stresses which make them leave their work at an age earlier than they might otherwise do. The Nuffield Foundation has rendered another public service in sponsoring this report

JOHN COHEN

The Pathogenesis of Poliomyelitis

By Prof. Harold K. Faber. (American Lecture Series—No. 257. A Monograph in American Lectures on Pediatrics.) Pp. xvi+157. (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1955.) 36*s*.

EXACTLY where the virus of poliomyelitis first invades the body has long been the subject of speculation, as also has the problem of its subsequent dissemination. These topics have for many years afforded a fruitful field for collaboration between anatomists and pathologists. The concept of the axonal transmission of poliomyelitis, first clearly formulated by Fairbrother and Hurst in 1930, soon met with the approval of Prof. H. K. Faber, who has staunchly advocated it ever since. The present work is a re-statement of his views, in the face of evidence which in recent years has appeared to cast doubt upon them.

His main thesis is that virus first enters the mucosa of the mouth and pharynx, and then spreads centripetally along the axons of sensory nerves to reach their ganglia, in which 24–48 hr. after exposure it begins to multiply. Two to three days later, the virus then reverses its direction and passes centrifugally to be excreted into the oropharynx, whence axonal re-invasion with further centripetal spread of virus may occur, while in addition varying amounts of virus are swallowed. Virus particles in the intestine, he suggests, may be absorbed in exactly the same way as undigested protein; and only thus do they reach the liver, or the intestinal and mesenteric lymphoid tissue, and the blood stream. Virus obtains access to the central nervous system either from the blood stream, or from the peripheral ganglia if they are severely infected.

Prof. Faber considers that the tissue culture experiments of Enders and his colleagues have no relevance to his argument. For though they showed that virus in tissue culture could grow outside the nervous system, and possibly in the complete absence of nervous tissue, Faber maintains that conditions *in vitro* and *in vivo* are fundamentally different. It is all the more surprising that he does not mention the experiments of German and Trask, which are especially pertinent in this connexion; nor does he seriously consider the possibility of cellular transport of virus mediated through the lymphoid tissues.

J. M. Yoffey

A Manual of the Dragonflies of North America (Anisoptera)

Including the Greater Antilles and the Provinces of the Mexican Border. By Prof. James G. Needham and Prof. Minter J. Westfall, Jr. Pp. xii+615. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1955.) 94*s*. net.

MORE than twenty-five years after the publication of his earlier book on the dragonflies of North America, Prof. J. G. Needham, in collaboration with Prof. M. J. Westfall, has now written the first part of a new and enlarged work, dealing with the sub-order Anisoptera. The need for it is evident from the fact that, since his first work, the list of species in the North American Anisoptera has grown from 245 to 332.

Most of the book naturally deals with the taxonomy of the group, but there are chapters devoted to the structure and life-history of the Anisoptera, to the methods employed for collecting adults and nymphs and for studying them in the field and laboratory. In the systematic part, keys and tables are given for the identification of families, genera and species (both adults and nymphs, where known), and under each species are given not only a description but also the principal bibliographic references, distribution and the period of flight of the adults.

The whole book is lavishly illustrated with line and half-tone illustrations of venation, genitalia and nymphs, all of a high level of excellence. Most of the photographs were taken by Prof. Westfall and were produced by the methods outlined in a joint paper with A. L. Smith (*J. Biol. Phot. Ass.*, 19, No. 2, 74; 1951). The manual will certainly be of great value, not only to American students of Odonata but also to others interested in these flies, and the publication of the companion volume on the Zygoptera, which is in preparation, is eagerly awaited.

D. E. Kimmins

Optical Instrumentation

Edited by Prof. George S. Monk and W. H. McCorkle. (National Nuclear Energy Series: Manhattan Project Technical Section. Division 4—Plutonium Project Record: Vol. 8.) Pp. xxv+262. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 30*s*.

THIS book is not of sufficient quality to justify the claim that it may be used as a text-book. The editorial advisory board finds it necessary to warn the reader to expect discrepancies and duplication on the plea that promptness of publication seemed more important: this is scarcely a recommendation for a reference book. Even so, it is a little too much to find that a smoke tester mentioned on p. 49 as being developed for particles 0·04 cm. in diameter is actually intended for particles $\frac{1}{4}\mu$ diameter according to paper 5.2 (not paper 5.3 as given by the reference). This paper makes the illuminating statement that cigar-smoke is the limit of precision of the method—the reader being left to draw his own conclusions. Techniques are mainly experimental and restricted both by time and to available lenses. It is thus not surprising to read on p. 15 "the best definition was not always obtained".

Theory is but briefly considered. In section 1.2, on brightness of images, it is stated that if the size of the entrance pupil is sufficiently larger than the exit pupil to compensate for light losses in the system, the intensity of a point object will be increased. The influence of the diameter of the pupil of the eye is not discussed. The book is not without interest, however: the problems encountered are outlined; the replacement of optical glass, darkened by high-energy radiation, by plastics is mentioned; and some valuable work on evaporation in vacuum is recorded.

G. W. Hamstead

The Ocean Floor

By Hans Pettersson. (Silliman Memorial Lectures.) Pp. xv+181. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1954.) 3 dollars; 24*s*. net.

ALTHOUGH the sea-floor covers approximately two-thirds of the Earth's surface, our knowledge of its morphology, structure and composition is meagre. For many years after the *Challenger* Expedition (1872–76) there was little progress, largely due to the lack of improved apparatus for investigating the deep-sea floor. Although the *Challenger* took cores 2 ft. in length, there was little improvement until Dr. B. Kullenberg, during the Second World

War, developed a piston core-sampler capable of taking cores 60 ft. in length. Prof. Hans Pettersson, realizing the significance of this and other recently developed geophysical techniques, organized with great success the Swedish Deep-Sea Expedition (1947–48).

This book, based on Prof. Pettersson's Silliman Lectures at Yale University, is a fascinating description of the scientific results of the Expedition, together with a summary of the results of other recent expeditions. Few technical terms have been used, and the book is intended for the non-specialist. The author's style is vigorous and clear, and his critical examination of theories is of great interest. There is an interesting chapter on deep-sea radium and the geochronology of the ocean floor. Since Pettersson's pioneer work on radium determinations, published in 1930, a possibility has existed of developing a time-scale for deep-sea cores based on radioactive decay. Piggot and Urry were first in this field. It would now seem from the detailed radium, ionium and uranium measurements that the problem is far more complicated than suggested by the investigations of Piggot and Urry.

J. D. H. Wiseman

Birds and Mammals of Shetland

By L. S. V. Venables and U. M. Venables. Pp. xii + 391 + 8 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1955.) 30*s*. net.

This is an ambitious book, the authors setting themselves the formidable task of describing the birds and mammals of that interesting northern group of islands known as the Shetlands; not content with this wide field, they give appendixes on the introduction of the common frog and common toad to Shetland, and they wind up with a list of plant flowering dates.

The volume begins with a short account of Shetland naturalists and visiting naturalists, goes on to consider Shetland habitats and then proceeds to status changes in Shetland birds. It is obvious that the authors take a keen interest in the waxing and waning of species and have found these islands an excellent place for population studies. After this, they work through the list of Shetland mammals and follow with the birds, dealing with them species by species in a very thorough manner.

They are to be congratulated on a painstaking effort and on a book that will be of much assistance to visitors to the islands.

Frances Pitt

Introduction to Virology

By Dr. Gilbert Dalldorf. Pp. ix + 102. (Springfield, Ill.: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1955.) 25*s*.

Dr. Gilbert Dalldorf's little book sets out to tell the practitioner and hospital pathologist the simpler facts about viruses and virus diseases of man. His hope is to convince them that virus infections can be studied, from the routine and even the research point of view, with the aid of comparatively simple equipment. He is very right to try to dispel the notion that it is an esoteric subject, only comprehensible to a select few. The commoner virus diseases are discussed from the clinical and laboratory aspects. Measles and chicken pox appear, oddly enough, under skin diseases and not under "Poxes and Rashes". "The Simple Common Techniques" are described, but scarcely in sufficient detail to allow of their being performed without reference to larger works, and unfortunately there are very few references. The word "subspecies" is used erroneously on p. 11; and on p. 59 and again on p. 87 the author makes the astonishing statement that latent infection with herpes simplex virus occurs frequently in normal rabbits.

Michelangelo

A Study in the Nature of Art. By Adrian Stokes. Pp. 154 + 24 plates. (London: Tavistock Publications, Ltd., 1955.) 25*s*. net.

This book is of somewhat unusual character, and perhaps valuable on that account. It is a brave effort to get beneath the surface of a tempestuous and majestic personality, that of Michelangelo (1475–1564). Unluckily, the author's style is often so obscure as to baffle the reader considerably, even if he is able and willing—as many readers will be—to see their subject in terms of Freud's psychology. The advantage, however, of this analytical study is, of course, that the basic nature of art—as a sensitive function of environment—is revealed stripped of adventitious material and is thus of æsthetic significance.

After some introductory matter, there is a discussion of the master's visual works, followed by an able analysis of his poems. There are copious notes, and a couple of appendixes, one concerned with iconography and the other with the Medici chapel. In addition, there are several illustrations.

All this leads to an appraisal of the unique contribution of Michelangelo to humanist art. Painting, sculpture, architecture, all bore witness to this tireless mind, melancholic and 'prickly', wearing itself out in superhuman feats of bodily endurance. His mannerisms were rugged, and as Lomazzo declared in 1590, Michelangelo reached the knowledge of harmonic proportions by way of music. Even his own body (on this showing) was built harmonically.

F. I. G. Rawlins

B.B.C. Handbook, 1956

Pp. 287. (London: British Broadcasting Corporation, 1955.) 5*s*.

This handbook, besides giving a general picture of broadcasting in Britain during the year ended March 31, 1955, and lists of representative programmes broadcast during that period, constitutes a very convenient reference work on the B.B.C. as well as a guide to its working. An account of the constitution is followed by notes on controversial and political broadcasting, and compared with last year's handbook there are fuller accounts of the External Services and of the re-broadcasting of the B.B.C. programmes throughout the world. More information is also included about the advisory councils and committees. Of particular interest to the scientist are the section describing the work and responsibilities of the Engineering Departments and that discussing some problems of reception, particularly very high frequency.

Details are given of the membership of the various councils and committees and of the senior staff, the balance sheet and accounts for the year, some analyses of income and expenditure, and tables of the totals and distribution of broadcasting licences, etc. The handbook includes the text of the royal charter, licence and agreement; and a good bibliography and index add to its value as an accessible and comprehensive source of information on the B.B.C. and its activities.

CYTOLOGICAL IDENTIFICATION OF RADIATION-CHIMÆRAS

By Dr. C. E. FORD, J. L. HAMERTON, D. W. H. BARNES and Dr. J. F. LOUTIT

Medical Research Council Radiobiological Research Unit, Atomic Energy Research Establishment,
Harwell, Berks

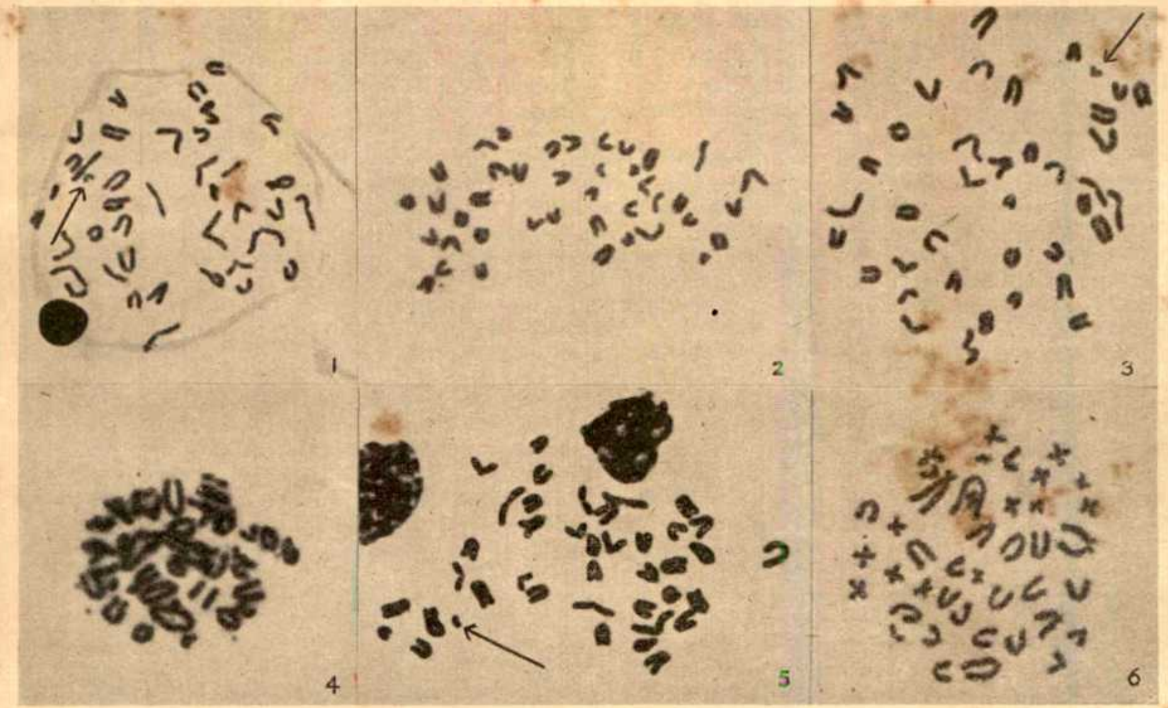
THE term chimæra, long used in botany, has recently been adopted by zoologists to denote an animal the constituent cells of which are of more than one genotypic or antigenic lineage. The state may occur naturally, as the freemartin in cattle. An example has even been reported in man[1]. It may be induced by the injection of foreign cells into the developing fœtus[2]. In all these instances it is believed that cells from one individual are grafted into another during fœtal life when the immunological mechanisms are immature. In these circumstances the natural and the foreign stock appear to be able to develop side by side. After the birth of the animal the effect of administering homologous cells or tissues changes and the homograft reaction occurs; following a preliminary 'take', the host develops an immune response and as a result sheds the graft.

It has been shown by Jacobson *et al.*[3], and soon after by Lorenz *et al.*[4], that adult mice irradiated with an expectedly lethal dose of X-rays could recover if grafted or injected with hæmopoietic tissue from a normal mouse. Consequently it was not surprising that they postulated recovery to be due to a 'humoral' or chemical factor in the material given, rather than to replacement of the damaged tissues of the host by foreign cells. Furthermore, Lorenz and his group showed that even heterospecific material from guinea pigs and rats could in some circumstances produce a similar result[5,6]. No example of the compatibility of a heterograft had been recorded, so the humoral theory seemed almost established. It received additional support from the investigations of Cole and his collaborators[7], who showed that homogenates in which the splenic material had been subjected to severe trauma were as effective as suspensions. On differential centrifugation of these homogenates the active fraction was the heaviest, consisting almost wholly of nuclei. The activity of this fraction was destroyed by solutions of crystalline deoxyribonuclease and trypsin, which were believed to act specifically on naked nuclei and not to damage any intact cells which might have been left after homogenization[8]. Cole and Ellis[9] considered the active principle to be macromolecular, particulate and probably deoxyribonucleoprotein.

On the other hand, there are the observations from our laboratory. Inbred mice irradiated and treated with homologous cells survive for short periods only compared with similar mice given isologous cells[10]. The material used for injection, normally very labile, is preserved by glycerol at -79° C.[11], as are some cells; and prior administration of homologous cells to elicit an immune response destroys the therapeutic effect of a second, post-irradiation injection of identical material[12]. When a single injection of homologous cells is made after irradiation, the donor's antigens persist and apparently increase in the host, and antibodies previously induced in the donor appear in the host and increase in titre (Mitchison, N. A., unpublished work). Recent experimental results obtained in the United States point in the same direction. A mixed population of erythrocytes with antigens derived either from host or from donor appears in the peripheral blood of irradiated rats given homologous bone-marrow[13]. Also, irradiated mice treated with homologous cells will tolerate selected skin grafts which normally they reject[14]. These experiments collectively give very strong support to the hypothesis that the damaged hæmopoietic tissues of the host are replaced by the injected foreign cells or their descendants. They fall short of proof, however, since they do not exclude the possibility that immunological properties may be transferred by a process akin to transduction in bacteria.

This objection would be overcome if dividing cells with one or more distinctive chromosomes characteristic of the donor could be identified in the host. The possibilities of such an experimental approach had long been appreciated in principle. The problems were technical and complementary; first, to find a suitable chromosome-marker, and second, to make preparations of a standard which would enable it to be recognized. There are forty chromosomes in a normal mouse. They show little differentiation, varying continuously in length and all having effectively terminal centromeres[15,16]. The sex chromosomes cannot be identified in somatic mitoses by present methods. It seemed, therefore, very unlikely that a satisfactory marker could be found in the mouse. However, in the course of a survey of the cytological properties of a series of semi-sterile stocks raised by Carter, Lyon and Phillips[17], one stock (*T*6) was found to be heterozygous for a very unequal reciprocal translocation between two of the smallest members of the normal chromosome-set. One of the two re-arranged chromosomes was thus much smaller than any of the normal complement and showed up prominently in spermatogonial metaphases. A potential marker having been obtained, the next step was to develop a really satisfactory technique for making preparations of bone-marrow. This proved more successful than had been anticipated and will be described elsewhere. It is sufficient to say here that it is an adaptation of the Feulgen-squash method, in which colchicine pretreatment is used and the tissue is handled as a cell-suspension. The small marker chromosome was found to be even more distinctive in bone-marrow cells than in spermatogonia (Fig. 1). It usually appears as three dots arranged in a triangle, suggesting the presence of an under-stained ('heterochromatic') region close to the centromere. Similar under-stained regions are found in five other chromosomes of the normal set. The chromosomes of a cell in metaphase from the bone-marrow of a normal *CBA* mouse are shown in Fig. 2.

Male *CBA* mice were used for the experiments. They were exposed to 950 r. of X-rays and then injected intravenously with a cell suspension prepared from the spleens of infant mice heterozygous



All the photographs are of cells in metaphase from bone-marrow, except Fig. 5, which is from spleen. Arrows point to the marker-chromosomes. Magnification × 960, except Fig. 4. Fig. 1: *T*6/+ mouse. Marker-chromosome present. Fig. 2: Normal *CBA* mouse. No marker-chromosome. Fig. 3: *T*6/+ cell in *CBA* mouse 14 days after irradiation (950 r.) and injection with *T*6/+ cells. Fig. 4: *CBA* mouse 5 days after irradiation (950 r.) and injection with *T*6/+ cells. Host cell showing dicentric chromosomes and acentric fragments. × 1120. Fig. 5: *CBA* mouse 28 days after irradiation (950 r.) and injection with *T*6/+ cells. *T*6/+ cell in spleen. Fig. 6: *CBA* mouse 19 days after irradiation (950 r.) and injection with cells from rat bone-marrow. Cell with normal rat chromosomes

for the *T*6 translocation. Eight animals in all have now been killed, at 5, 14, 19, 28 and 49 days after injection, and in every one the characteristic *T*6 marker-chromosome has been found in dividing cells of the bone-marrow. A typical cell from an animal killed 14 days after injection is shown in Fig. 3. In such a cell it is possible to count the chromosomes accurately and to be quite certain whether the marker-chromosome is, or is not, present. Cells descended from those injected are in any event positively identified by the marker-chromosome, whether the chromosomes are countable or not. A disadvantage inherent in the squash-technique is that one can never be quite sure when a cell has been broken and some of the chromosomes lost. The firm identification of a host cell therefore requires the presence of a full and normal set of mouse-chromosomes (that is, a count of 40 and no marker). No such normal cell has yet been found. However, structural changes of the kinds well known to be induced by irradiation have been observed in a few cells. It is reasonable to attribute these changes to the high dose of radiation delivered to the host-animal and so to identify the cells containing them as host cells. An example is shown in Fig. 4. This cell is broken and only thirty-six of the centromeres can be accounted for. Nevertheless, eight dicentric chromosomes, fourteen acentric fragments, and four pairs of minute (isodiametric) fragments were found. It may be noted in passing that if a cell such as this is able to complete division the daughter-cells would be so unbalanced genotypically that the possibility of their survival must be very remote.

The marker was readily identified in the great majority of cells with well-spread chromosomes. Many of these cells contained forty chromosomes; none had more; some had less. Most of the latter had clearly been broken during the making of the preparations. The relatively few cells lacking a marker had counts of less than forty. In addition, dividing cells with chromosomes insufficiently spread for accurate counting were present in all preparations. The marker was identified in many of these also, although a careful search was often necessary. No essential difference was noted between animals killed at different times. These results show that at least a large part of the host's bone-marrow had been replaced by cells originating from the donor, and that there is no evidence of recovery of the host's own tissue even seven weeks after injection.

Dividing cells containing the marker-chromosome have also been identified in spleen (Fig. 5), lymph node and thymus. The information for these tissues is not yet as extensive as for bone-marrow. Nevertheless, it suggests that the situation in these organs is essentially the same, that is, virtually complete replacement of the host's tissue by donor-cells. It is significant that, in comparable experiments, Mitchison (unpublished work) found antigenic activity attributable to the donor to be present in spleen and lymph node for as long as seven weeks after injection.

One series of irradiated mice was injected with a suspension of bone-marrow cells of the Wistar rat and killed 5, 11 and 19 days afterwards, two at each time. Dividing cells with normal rat-chromosomes were easily identified in bone-marrow from all the animals (see Fig. 6). The chromosome complements of the rat and the mouse are strikingly different, and almost all cells at metaphase could be firmly identified one way or the other. Of 1,400 cells examined, none was identified as a mouse-cell and only fifteen were classed as uncertain; all the remainder contained rat chromosomes. This result confirms and extends the conclusion to be drawn from the experiments with the *T6* marker, namely, that replacement of the host's bone-marrow by injected donor-cells is effectively complete.

These results would seem to establish finally that cellular repopulation is the mechanism by which spleen and other tissues bring about their therapeutic effect. They do not, however, specifically exclude the possibility of simultaneous operation of a humoral factor. The role that such a factor might take is now problematical, since it could scarcely still be maintained that it was concerned with recovery of the host's hæmopoietic tissue, as originally postulated by Jacobson. Recovery by cellular repopulation is not incompatible with the reports that suspensions of free nuclei are active; but consideration of the way in which free nuclei might exercise a therapeutic effect is unnecessary until it is conclusively demonstrated that the action cannot be attributed to the presence of some intact cells in the preparations. Although the main question, we believe, is now firmly answered, it remains to be determined whether there is some measure of recovery by the host's own cells at an even later stage than we have yet been able to examine.

That a therapeutic effect could be obtained by injection of heterologous material has been known for several years[5,6]. In fact, this was at one time considered by some workers to be almost decisive evidence in favour of the 'humoral' hypothesis. Those who preferred the alternative view must have been prepared to accept the unorthodox concept of the co-operation, at least temporarily, of the cells of two distinct species in one individual. Although the very term chimæra points to the antiquity of the idea, it is believed that the experiment reported here provides the first decisive evidence in animals that normal cells of one species may, in special circumstances, not merely survive and multiply in another, but even replace the corresponding cells of the host and take over their functions.

The possible applications of the chromosome marker technique are worth noting. In principle, it provides a biological 'tracer' method which should be applicable to all questions where the origin in development or regeneration of a particular group of cells is at issue, provided the cells concerned undergo mitosis naturally, or can be persuaded to do so. It may also find applications in connexion with problems of carcinogenesis and transferred immunity. The method might be applied in two ways: by injection or implantation of cells already carrying a marker, or by localized irradiation to produce a detectable, viable chromosome rearrangement *in situ*. The latter method has already been employed in plants by Brumfield in an attempt to determine the number of primary generative cells in the root meristem of *Vicia faba*[18].

We have been greatly helped by the advice and interest of many of our colleagues, especially Dr. R. H. Mole and Dr. E. V. Hulse. The heterozygous *T6*/+ mice were kindly provided by Dr. T. C. Carter, Dr. M. F. Lyon and Miss R. J. S. Phillips.

Addendum. A report[19] received after this manuscript was completed describes the detection of alkaline phosphatase activity characteristic of the rat in cells from irradiated mice injected with rat bone-marrow. Although the authors regard repopulation of the host's bone-marrow by cells from the donor as the most likely explanation of their results, they point out that induction of the observed changes in the host's own cells is not excluded.

THE *ATLANTIS* MARINE GEOLOGICAL EXPEDITION TO PERU AND CHILE

By Dr. PARKER D. TRASK
Department of Engineering, University of California

THE research vessel *Atlantis*, of Woods Hole Oceanographic Institution, explored the deep trenches that lie off the coast of Peru and northern Chile during November and December 1955. The expedition collected a hundred cores of sediments along twelve profiles between Talara in lat. 5° S. to a point eighty miles south of Antofagasta, Chile, in lat. 25° S. Continuous soundings of the water depth were made with the new Woods Hole sensitive sonic sounder whenever the ship was under way. In addition to the profiles on which sediments were collected, six traverses solely for sonic sounding were made across the deepest part of the trenches. Numerous bathythermograph readings were made of the Humboldt Current, and twelve runs were made with the geomagnetic electrokinetograph south of Iquique, Chile, in lat. 20° S. in an effort to determine the strength and character of the Humboldt Current. These are among the first runs of this character that have been made south of the magnetic equator, which passes near Lima, Peru. The results have not yet been calibrated to indicate the actual character of the current.

One of the most interesting features of the Expedition was the delineation, by means of the sonic sounder, of a trench 500 miles in length and one to three miles wide, and 24,000–26,000 ft.—mostly more than 25,000 ft.—deep extending between Arica in lat. 19° S. and lat. 25° S. The sides of this trench in each of the seven places where it was crossed are remarkably steep and range in height from 1,000 to 4,000 ft. In one place in lat. 25° S., the wall of the trench, as indicated by the fathometer trace, rose 1,500 ft. in a quarter of a mile. This trench was only forty miles from shore at this locality. The trench is balanced by mountains 20,000 ft. high scarcely 125 miles away. North of lat. 19° S. this trench is shallower and evidently is offset on echelon by a shallower trench to the west.

The sea floor seaward from shore descended more or less progressively to the bottom of the trench. In many places remarkably flat benches were observed in water from a few hundred to several thousand feet deep. These benches in places were terminated by more or less pronounced scarps, some of which were steep and as much as 5,000 ft. in height. Seaward from the deepest part of the trench the bottom rises more or less progressively upward to a depth of 2,200–2,000 fathoms. The tracings of the sonic recorder give the impression that the deep trench represents a graben within other downfaulted blocks, such as is found in the Red Sea.

A profile was run parallel to the coast between lat. 12° S. and 26° S. in shallow water. One large submarine canyon with walls 3,000 ft. in height was found. It is located a short distance north of Arica, about lat. 18°. Elsewhere only occasional minor notches are observed in the profiles parallel to the coast.

The primary objective of the Expedition was to study the sediments. The deepness of the troughs suggests that the area represents a geosyncline in the making. The land that is the source of the sediments for the area is arid and supplies relatively little sediment to the sea. It is hoped that the results will throw light on the origin of greywackes. Details of sedimentation cannot yet be given as the sediments were kept in the core tubes until return to the laboratory; but many of the samples, particularly in water of shallow and intermediate depth, consisted of muddy sands strongly suggestive of greywacke. Certainly the pattern of sedimentation does not accord with the concept of increasing fineness from shore. In many places the sediments at some distance from shore are much coarser than those nearer the coast. The deep samples consisted of clays in all cores except one, which was sandy. The cause of the variation in texture is not apparent from the field-observations. Perhaps bottom configuration is a factor.

Three cores were placed in a refrigerator as soon as collected to prevent decomposition of possible hydrocarbons. It is hoped that studies of the organic content of these frozen samples will throw light on the origin of oil.

The Expedition was conducted under the auspices of Woods Hole Oceanographic Institution of Woods Hole, Massachusetts. The Esso Research and Engineering Co. and Socony-Vacuum Laboratories have also contributed to the support of the project. The Esso Research and Engineering Co. hopes to assist with the studies of the hydrocarbon content of the sediments. Henry C. Stetson, research oceanographer of Woods Hole Oceanographic Institution and Alexander Agassiz Fellow in Oceanography, Museum of Comparative Zoology, Harvard University, was chief scientist in charge of the Expedition until his unfortunate death at sea on December 3. Parker D. Trask, research associate of Woods Hole Oceanographic Institution and lecturer in geologic engineering of the Department of Engineering of the University of California, was chief scientist for the remainder of the trip. Other members of the scientific staff included Bernhard Kummel, associate professor of stratigraphy and palæontology, Harvard University, and the following staff members of Woods Hole Oceanographic Institution: William D. Athearn, Robert Lufburrow, Herbert Small and John Zeigler. Victor Benavides, geologist of the International Petroleum Company of Peru, Lieut. Jose Carvajal of the Peruvian Navy, and Jose Stuardo of the Chilean Marine Laboratory at Valparaiso, also participated in the work.

This study was supported mainly by the Office of Naval Research.

RESEARCH STUDENTS IN THE UNITED STATES OF AMERICA

By H. N. V. TEMPERLEY
Riversdale, Grantchester, Cambridge

THIS article is written after three extended visits to the United States. I spent seven months at Yale, a whole academic year at the University of Nebraska and about six months at the Bureau of Standards, Washington. In addition, I made shorter visits to about fifteen other universities and research institutions. In Britain I have had a total of about ten years experience in directing small research groups in the Admiralty and at Cambridge.

So far as physics and chemistry are concerned, it seems to me that standards for a Ph.D. degree do not vary greatly as between different universities, nor are there very wide differences as between Britain and the United States. It is widely recognized by employers that these letters guarantee a considerable innate ability and capacity for hard work. It is, I think, fairly generally agreed that the American freshman is not nearly so well prepared for college as is his English cousin, but some of the difference has already been made up at the 'bachelor' stage, because of the fact that the degree course lasts four years instead of three; the remaining small difference, if any, is probably wiped out during the Ph.D. course, which can seldom be completed in less than four years even by a very brilliant student. Many universities encourage even their very good undergraduates to do their graduate work elsewhere, in contrast with the inbreeding tendency at British universities. This means that several months may be spent in moving a home and getting used to new conditions; but this is not the main reason why the course tends to be longer than in Britain. The American graduate student is usually forced to complete a relatively large number of lecture-courses and examinations before he can even apply for permission to submit a thesis. Some of this work represents material that the British undergraduate would have covered in his last year; but a considerable difference remains in practice, even when full allowance is made for this fact. Indeed this is one of the main differences in the 'conditions of work' of graduate students in the United States and Britain; and it is arguable that the British tendency to leave the research student to plan his own attendances at lectures goes too far to the other extreme.

The differences in the arrangements for choosing graduate students, looking after their welfare, providing them with advisers, and for the refereeing and evaluation of their theses are not great and call for correspondingly little comment. The methods by which a scholar of distinction sets up and organizes a school of research workers have probably not greatly changed down the ages, since the main requirements of attracting recruits and of creating and maintaining a satisfactory personal relationship between the research director and the members of his team have always existed. The problems which it leads to, such as keeping temperamental people working happily together, avoiding bullying and yet seeing that everyone has a worth-while problem to work on, and seeing that everyone gets proper credit for his special contributions, are more difficult to-day, because of the increasing tendency to work in large teams, which is itself a result of modern trends in research. (Disaster occasionally results from too great an expansion of a flourishing team.) The other really striking difference in 'conditions of work' is a purely material one. The American graduate student in the physical sciences can confidently expect better offers than can his British cousin, once the 'period of apprenticeship' is completed; but, during this period, he has a decidedly harder and rougher time. The newly qualified Ph.D. can expect several offers from industry in the region of 5,000–7,000 dollars, while a teaching post in a school, or a government post, might pay around 3,000–5,000 dollars, and a post-doctoral fellowship or junior instructorship would be worth about the same. (In purchasing power 4 dollars are roughly equivalent to £1.) As in Britain, there is considerable competition for the junior academic posts and post-doctoral fellowships; but the number of industrial vacancies far exceeds the supply of men, and, since the Second World War, quite a number of firms have been forced into a quite new line of 'sales-talk': 'Come and look at us and at the splendid laboratories and fine conditions of work we offer you'. All this may seem to compare very favourably with the £500–£700 which seems to be the market value of the newly qualified British Ph.D. Various other factors have also to be considered, such as the fact that Americans marry younger, the differing incidence of taxation and the existence of a National Health Service in Britain; but, taken all together, they probably do not greatly change the overall picture. (The fear of a sudden illness and a large hospital bill is a very real one to many young American families, and numerous insurance schemes exist with the object of lessening this source of worry.)

The British graduate who wants to do research and can get himself accepted by a university at all can nearly always cover his living expenses and fees by means of scholarships or a government grant, without being specifically required to do any teaching or other work outside his research. Indeed, strict limits are usually set on the amount of teaching he may do, and other work is often forbidden altogether. This contrasts very strongly with the position of the American graduate student. There are, of course, innumerable endowed scholarships and loan funds: but these are usually for quite small amounts, and roughly speaking, there are three ways by which a graduate student can hope to cover the main expenses of his research course. He may become a member of a team in his department that is working on some specific research project financed from outside, usually by the government. He may take a part-time job in the same way as an undergraduate student; or, finally, he may be appointed a 'graduate assistant' by his department. This last type of post resembles the British one of student-demonstrator. A typical stipend would be 1,500 dollars, for which he is expected to give almost as much time to teaching as does a full member of the staff. This will usually consist mainly of laboratory demonstrating and the conducting of 'recitations' (that is, supervising examples classes held in conjunction with the lectures) but nearly always includes some formal lecturing. Add to this the fact that, as we have seen, he also has to pass various examinations and to pile up a fairly impressive record of attendance at advanced lectures as well as keeping himself informed on his own special field, and the wonder is that he has time for original thought at all. It is possible for a single man to live on his stipend; but, if a graduate assistant is married and without private means, it is practically essential for the wife to take paid work. This she fully expects to do, and she will often earn more than her husband! It is probably fair to say that the average American Ph.D. thesis contains more 'padding' and undigested material and fewer original ideas than does its British counterpart; but it has almost certainly been produced under more difficult conditions.

It is not easy to compare the merits of the two systems. They are conditioned partly by the differences in the raw material that the colleges receive from the schools, which ultimately means that certain ground that is covered by undergraduates in Britain has to be left until the graduate student stage in America. Apart from this, any university that reduced its requirements for the Ph.D. degree to any great extent would lay itself open to the very damaging gibe of being a 'degree pedlar'. The fear of 'losing face' in this way is obviously a very real one, and makes any big change in standards difficult, even if it were desirable. I am fairly sure that I did not visit, or even hear of, any institution where a Ph.D. was obtainable without a great deal of hard work. One problem seems to be common to both systems, and in fact both systems handle it in a rather haphazard and piecemeal way, probably because no simple solution has ever been found. Although it may seem strange to say it, the problem is that of making the best use of the 'pure researcher', once he has qualified for his doctorate. How is he to be found an honourable and reasonably secure place in society, and at the same time prevented from becoming a crank or charlatan, or an inventor of impossible gadgets or a mere drone? Many solutions to this problem have been tried in the past, such as private patronage of learning, monastic communities of various kinds, life-fellowships of colleges. Probably we are in the process of evolving a new arrangement on both sides of the Atlantic, something in keeping with the enormous expansion of research.

How does such a man fit into the American scene? He is probably good enough to be considered for a post-doctoral fellowship, but these seldom last for more than a few years. He may get congenial work as a member of a research group working in a university laboratory but financed by one of the big government agencies such as the Atomic Energy Commission, the Office of Naval Research or the National Science Foundation. The difficulty here is that funds are usually allocated annually and Congress can, and often does, impose cuts in the budgets of such agencies. Even apart from this, there is the fundamental difficulty that, before each year's money is handed out, there must have been a contact, somewhere along the line, between someone who understands just what the particular research project is all about and someone who does not but who may have power to reduce or withhold the next grant, or to divert the money to some other project. Much time and effort is obviously spent in trying to be fair about 'evaluating' reports on the work of the past year and also 'projects' for fresh research, which seems to be done mainly on the basis of referees' reports (I was asked to make a few myself); but it all produces a decided sense of insecurity for the people who are doing the work, knowing, as they do, that a grant may easily be cut next year for reasons totally unconnected with the merits of the work or its value to the community. Another possibility is an industrial or government post. Here, the short-term position is more secure; but most employers, quite understandably, expect a research department to perform a considerable amount of 'bread-and-butter work' which may be anything from routine testing to the development of a new plant on the pilot scale or the designing of circuits for a special requirement. Much depends here upon the director of the laboratory and on his ability to act as a buffer between his staff, who want to investigate interesting long-term problems, and his board, who naturally expect some visible return for the expenditure they are asked to approve. The final possibility is the traditional one of an academic post; but this is far from an ideal solution in present conditions. In these days of rapid expansion of demand for engineers, physicists and chemists the young instructor is likely to be faced with a heavy load of elementary teaching, and the fact that he has research ability does not necessarily mean that he has interest in, or aptitude for, pure teaching at an elementary level; nor does the fact that he is an expert at designing and using apparatus necessarily mean that he is capable of keeping a practical class running smoothly. If he has a young family, he is likely to find his stipend barely enough to live on, and he will be forced to take on yet more teaching during the 'summer sessions', or else to do other paid work during the three summer months. (I knew one young professor, in this position, who was selling copies of a famous encyclopædia as a sideline.) A few universities do have research professorships, while others will arrange that a distinguished scholar has a very light teaching load; but, with nearly all his time occupied, how can the young instructor hope to do the work that will gain him the reputation that would win him one of these coveted posts?

Be all this as it may, there can be no doubt that the 'lure of the ivory tower' is still immensely strong, and that one of the dearest wishes of many a bright student is to be asked to return to his university or college as a junior instructor. Anyone who doubts this must explain how it is that even quite small and obscure colleges seem to have little difficulty in filling their vacancies. Very little formal advertising is done, deans usually notifying one another of vacancies by means of circular letters. Contrast this with the fact that industrial firms who are in a position to offer better pay, probably coupled, as we have seen, with more time for research, are resorting more and more to publicity stunts in order to attract applicants. The explanation is probably two-fold. The scholar who has a real vocation for teaching and pride in training future leaders of men is, as he always has been, willing to work for less than his true market value and to face the drudgery of teaching large elementary classes. The scholar whose main ability lies in research feels sure that, in the long run, the universities will always be the real homes of fundamental research, and that, in due course, some of the very real difficulties outlined above will be sorted out. It does seem certain that the financing of research at the universities by outside bodies has come to stay, and that, in time, reasonable means will be evolved for regulating the inflow of money. The phrase 'going industrial' is often applied to a scientist who leaves academic life. It seems to convey not so much a feeling of superiority, but a subtle tinge of sorrow that one more good man has sold part of his soul.

A more disturbing point concerns the number of British physicists and chemists who are tempted, by the higher pay and lower taxation, to settle in the United States on a long-term basis. There is everything to be said for interchanges and visiting posts; but, in present conditions, it is hard to see how a prolonged stay can benefit either country in the long run.

OBITUARIES

Prof. Hermann Weyl, For.Mem.R.S.

Among all the mathematicians who began their working lives in the twentieth century, Hermann Weyl was the one who made major contributions in the greatest number of different fields. He alone could stand comparison with the last great universal mathematicians of the nineteenth century, Hilbert and Poincaré. So long as he was alive, he embodied a living contact between the main lines of advance in pure mathematics and in theoretical physics. Now he is dead, the contact is broken, and our hopes of comprehending the physical universe by a direct use of creative mathematical imagination are for the time being ended.

Weyl was fortunate in the manner of his death. On November 9, 1955, he celebrated his seventieth birthday, in full and robust health of body and mind. At the banquet which was given in his honour in Zurich, he received messages of goodwill and homage from all over the world. Less than a month later, on December 8, he walked out of his house to post a letter, suffered a heart-failure, and died instantly.

The beginning of Weyl's scientific life cannot be better described than in his own words. "I came to Göttingen as a country lad of eighteen, having chosen that university mainly because the director of my high school happened to be a cousin of Hilbert's and had given me a letter of recommendation to him. In the fullness of my innocence and ignorance I made bold to take the course Hilbert had announced for that term, on the notion of number and the quadrature of the circle. Most of it went straight over my head. But the doors of a new world swung open for me, and I had not sat long at Hilbert's feet before the resolution formed itself in my young heart that I must by all means read and study whatever this man had written. And after the first year I went home with Hilbert's 'Zahlbericht' under my arm, and during the summer vacation I worked my way through it. These were the happiest months of my life, whose shine, across years burdened with our common share of doubt and failure, still comforts my soul." The words "read and study whatever this man had written" are the key to Weyl's breadth and versatility. Hilbert's method of work was to choose a field of mathematics, study it intensely for a few years, revolutionize it with a basic new idea, then drop it and look for another field. Weyl followed the same method, and was equally successful.

The following is a very incomplete chronological summary of Weyl's activity. Between 1908 and 1917 he worked on problems in classical pure mathematics, in particular the theory of numbers, singular integral equations, and functions of a complex variable. His book "Die Idee der Riemannschen Flache" created a new branch of mathematics by uniting function-theory and geometry; the influence of this book led directly to a synoptic view of analysis, geometry and topology which has become a central theme in the mathematics of to-day. During 1917–23 he worked on the logical foundations of mathematics, and simultaneously took an active part in the development of Einstein's relativity theory and its generalizations. He discovered the first 'unified field theory' in which the Maxwell field appears along with the gravitational field as a geometrical property of space-time. This theory he soon rejected as being without empirical foundation; but it remains at least as plausible as any of the other unified theories which came later. Between 1923 and 1938 he created a general theory of matrix representations of continuous groups, which powerfully assisted the growth of quantum mechanics. He discovered that a large proportion of the regularities of quantum phenomena in atomic physics can be understood most simply by means of group theory. By bringing group theory into quantum mechanics he led the way to our modern style of thinking in physics. To-day the instinctive reaction of every theoretical physicist, confronted with an unexplained regularity in the behaviour of elementary particles, is to postulate an underlying symmetry-group.

After taking his degree at Göttingen, Weyl occupied chairs successively at the Federal Technical College in Zurich (1913–30), at Göttingen (1930–33), and at the Institute for Advanced Study in Princeton (1933–51). He was elected a foreign member of the Royal Society in 1936. He was twice married, and is survived by a widow and two sons.

Characteristic of Weyl was an æsthetic sense which dominated his thinking on all subjects. He once said to me, half joking, "My work always tried to unite the true with the beautiful; but when I had to choose one or the other, I usually chose the beautiful". This remark sums up his personality perfectly. It shows his profound faith in an ultimate harmony of Nature, in which the laws should inevitably express themselves in a mathematically beautiful form. It shows also his recognition of human frailty, and his humour, which always stopped him short of being pompous. His friends in Princeton will remember him as he was when I last saw him, at the Spring Dance of the Institute for Advanced Study last April: a big jovial man, enjoying himself splendidly, his cheerful face and his light step giving no hint of his sixty-nine years.

FREEMAN J. DYSON

Prof. H. Oertel

PROF. HORST OERTEL, who died on January 9 at the age of eighty-two, was formerly Strathcona professor of pathology in McGill University. Since leaving Canada in 1938, he had lived a retired life at his club in London.

Although born in Germany, near Dresden, Oertel received most of his education in the United States and took his medical degree at Yale in 1894. Shortly afterwards, he returned to Germany for postgraduate studies, first at Berlin, where he was much influenced by Virchow and Senator, and later, at Wurzburg and Leipzig. His interest in philosophy, which continued throughout his life, was greatly strengthened by his contact with Wundt, whose reputation as an exponent of physiological psychology was then drawing students and research workers from many parts of the world.

Soon after his return to the United States in 1897, Oertel became the director of a department of pathology—later the Russell Sage Institute—that was then being developed in a large municipal hospital under the auspices of the New York University School of Medicine. In 1911, political changes in the city brought this association to an end, though Oertel maintained for some time longer his connexion with the Russell Sage Foundation. Much of his work at this time was upon nephritis, to the study of which he had been stimulated by Senator, and in 1910 he published a series of lectures on Bright's disease. It was this interest, too, that brought him to London in 1913 to work at Guy's Hospital—near Bright's own wards—on experimental nephritis and the embryology of the kidney. This "delightful and profitable departure", to use his own words, brought him into association with Laidlaw, Boycott, Keith and Assheton. In 1914, while still in London, Oertel received an invitation to an associate professorship at McGill University under J. G. Adami. Almost at once, he assumed full direction of the Department, for Adami left Montreal soon afterwards, first for war service and later to become vice-chancellor of the University of Liverpool.

At McGill, Oertel quickly developed an active pathological institute in close association with the Royal Victoria Hospital, and it was here that his most productive work was done. His previous experience in the United States, Germany and England had led him to a critical appraisal of the objectives of medical education at a time when the scope of the curriculum was being widened at an unprecedented rate. His tenure at McGill gave him the opportunity to put some of his views upon teaching into practice. These ideas soon gained a wider audience through the publication in 1921 of his "General Pathology", a book which was followed in 1927 by "Outlines of Pathology" and in 1938 by "Special Pathological Anatomy". All three bear the distinctive marks of Oertel's personality—his absorption with the historical development of pathology and its emergence as an independent biological science. Although addressed to undergraduates, their scholarly character can only be properly appreciated by those of wider experience and fuller knowledge of the progressive emancipation of this medical science from its pragmatic origins.

The formative period of Oertel's life was at the time when many young graduates in the United States had come to realize the impact on medicine of the remarkable developments that had taken place during the later nineteenth century in Germany as a result of the mutual fertilization of the medical and fundamental biological sciences. Although to him a problem in pathology always appealed as a scientific inquiry that took origin from a wish for a better understanding of causal phenomena in disease, he showed none of that lack of appreciation, not unknown among medical scientists, of the humanitarian demands of medicine. But, like some of the more far-seeing of his contemporaries in his country of adoption, he came early to realize that natural philosophy does not necessarily lose its interest by possessing useful applications, and that efforts to solve the problems presented by disease are not necessarily without intellectual attraction. It was the effort to combine the searchings of the philosopher with the responsibility of the physician that distinguished Oertel's contributions to pathology.

G. Payling Wright

Mr. Sidney G. Starling

Sidney G. Starling died on December 16, at the age of eighty-two. He was born in Bradford and received his early education at the Grammar School and Technical College. Having obtained an exhibition and national scholarship, he entered the Royal College of Science, London, in 1891 under Prof. Rücker. Here he secured first-class honours, prizes and medals and worked as assistant and demonstrator during 1893–95. Working under C. V. Boys, he undertook the calculations required for the determination of the Newtonian constant of gravitation. Between 1895 and 1898 he was assistant lecturer in mathematics and physics at Battersea Polytechnic, during which time he graduated at the University of London and was awarded the Neil Arnott Exhibition and Medal. At the opening of the West Ham Technical Institute in 1898, he was appointed the first head of the Department of Physics and Mathematics, a post he held until his retirement in 1932. In 1899 he married Miss M. Briggs, who was an assistant in the Art Department at Battersea.

Throughout his lifetime, he was an active member of the Board of Studies in Physics in the University of London and a member of the Faculty of Science. In his earlier years he was an extensive abstractor of Continental papers for the Institution of Electrical Engineers and the Physical Society of London. In 1920 he was elected Fellow of the Institute of Physics.

Starling is probably most widely known as a writer of text-books of physics. The association of Duncan (the engineer) with Starling (the physicist) in the production of their "Text Book of Physics" (1918) was suggested by Sir Richard Gregory, of whom Starling was a great friend. Starling's own "Electricity and Magnetism for Advanced Students" (1912) has been a standard text-book throughout the years, appearing in many editions, the latest being revised in collaboration with A. J. Woodall in 1953. During his retirement there have appeared "Mechanical Properties of Matter" (1935), "Physics" (in collaboration with A. J. Woodall, 1950) and a revision of "Science in the Service of Man—Electricity" (in association with his son-in-law, H. J. Gray, 1949).

Staff and students respected Starling for his sympathetic understanding, scientific integrity and the quiet efficient way he solved technical and organization problems. There was not the slightest procrastination or duplication of effort. He was a strict disciplinarian and a stickler for punctuality. The ease with which he could erect apparatus for research or demonstration was particularly noteworthy. His published researches and writings do not convey his skill and versatility in this direction. In particular, he did pioneer work on aeroplane compasses (theoretical and experimental) at the time of the First World War.

All his hobbies were characterized by high achievement with apparently little exertion, ranging from shooting, golf and photography to silver smithing. From 1912 he had taken a very active part in Freemasonry. Only his closest friends will have appreciated his keen sense of humour, and even they can scarcely realize the many kindly acts of sympathy and encouragement he rendered to those in adversity. He is survived by a son and daughter.

William Swaine

Dr. George Slater

Dr. George Slater, one of the leading glaciologists of Great Britain, died at the age of eighty-one on January 27. He started his geological career when a schoolboy at St. John's College, York. Later, he continued as an amateur geologist while a schoolmaster at Haltwhistle, Northumberland (1895–97), and at Ipswich (1897–1918). He showed an early interest in palæontology, but at Ipswich, to quote Dr. F. A. Bather, he "became entangled with the complicated drifts of Suffolk". Patiently he mapped and recorded the structures seen in these disturbed drifts, in temporary sections, on successive faces in sand-pits and, during the First World War, in trenches dug for Army training. Though he published little during this early period, he became recognized as an authority on the glacial drifts of East Anglia, and in 1907 and 1911 led field excursions of the Geologists' Association at Ipswich.

He entered the Imperial College (Royal College of Science) in 1918 and remained a member of the geological staff until his retirement in 1939, having obtained the degree of D.Sc. (London) in 1926. The Geological Society awarded him the Murchison Fund in 1928, and in 1950 he received the Foulerton Award of the Geologists' Association.
